The results of the study showed a sophisticated cognitive analysis of the situation by the students. In almost all cases they were able to give plausible arguments concerning the notation of results, the number of necessary readings or the routines of data calculation. The discussion of the uncertainty of measurement played only a minor role in their arguments and decision processes. For example, less than a third of the students referred to the limited precision and accuracy of the measurements when comparing different results, or when comparing them with a reference value. The uncertainty of the result in the latter cases was mostly established by estimating the deviation of the result from the reference value. These results confirmed the findings of prior studies by Séré & Larcher (1993), Buffler *et al.* (2001), Campbell *et al.* (2001) and Volkwyn *et al.* (2008) and gave some additional insight as to how the students would assess the accuracy and precision of their data if they did not use the concept of uncertainty. Rather, they employed arguments concerning the numerical values only, different kinds of rules etc. All in all, five different areas of action-guiding cognitions were isolated where students drew their information from in order to answer the questions. Those five areas contained references to either:

- the analysis of the experimental realization,
- the consideration the process of data production,
- the conduction of evaluation procedures,
- the result-based comparisons to a reference value or
- the application of normative rules

These categories gave rise to the *model of action-guiding cognitions* described above and presented in **Erreur ! Source du renvoi introuvable.**. (Four puzzle represent the first four categories and highlight the need of interconnection between them. The fifth forms a framework of formal-normative rules.) The results were also supported by an accompanying study of 151 physics students at German universities who were asked to fill in the online questionnaire as well. This was done to check the results of the triangulation study for (e.g. regional) reliability.

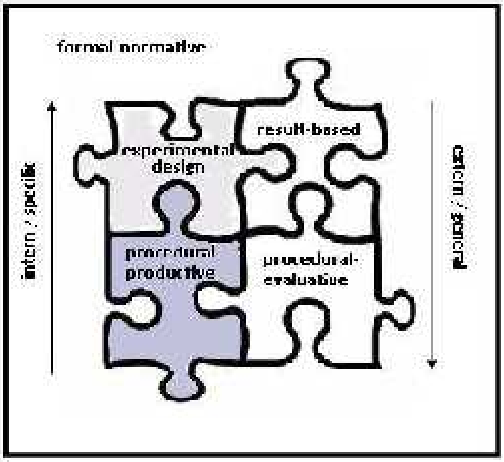

Figure 1: Model of action-guiding cognitions in the experimental context.

To illustrate the five areas of the model, we can use examples from the questionnaire. For instance, the students were asked to decide and justify whether they would repeat a measurement or leave the result to the one measurement already obtained. In the formal-normative frame focusing on the formal and theoretical aspects of experimental work – like rules, routines and boundary conditions – a typical answer would be*: „One always has to conduct any experiment three times."* A result-based argument would rather focus on the obtained numerical result of the measurand, e.g.: *„No, my result is close enough to the literature value,"* or *„I would measure again to check my result."* In contrast, a procedural-evaluative argument would focus on the evaluation routines, e.g.: *„I would repeat the measurement to get enough data for the calculations of a mean (and its uncertainty)."* In the procedural-productive area, an argument highlights the origin and history of the obtained result: *„I would repeat it if I knew that something happened during the previous measurement or if it showed some uncertainties / statistical fluctuations."* Lastly, the area of the experimental design focuses on the significance of the experimental realization: *„Probably the electric current will not stay constant all the time, so it would be wise to repeat the measurement a couple of times."*

The model proved helpful in understanding a new aspect of the students' difficulties in their understanding of the handling of data and measurement uncertainty that had not been elaborated on by former studies. It showed that not only could those different areas be distinguished in the students' reasoning but also that almost no argumentative links between the different areas were drawn in the students' answers.

Of course, one might argue that it was not mandatory to cover all or even many of the areas in every argument on measurement data and uncertainty. However, the lack of links between the five areas indicates more extensive difficulties. Those difficulties become more obvious when consulting the further results of the triangulation study. The results show that the missing links between the five areas run deep not only in the situative argumentation but in the students' understanding of the matter.

Comparison of reasoning on action and reasoning in action: missing links

The results of the second part of the study were thus quite unexpected. While all but three of the 32 students had argued in the written survey that the experiment had to be conducted more than once, the practical task showed distinctly different results. Only four out of 13 groups actually conducted a reading of the same shape of the curvature more than once. Even more surprising was that in none of these four cases this approach was heralded by any discussion on the experimental set-up, on the expected data fluctuations or even general remarks on experimental methods, let alone measurement uncertainty. Of those four groups, one decided on a threefold repetition due to some rule that “you always conduct three runs” and the repetitions of the other three merely happened by chance, e.g. because the experimenters could not agree on the result of the first run and decided to take another roll – only to notice that the second roll agreed with neither of their expectations. Just the same, the discussion of uncertainty played yet a minor role in most of the written surveys, however, in some or the other form it appeared in about half. On the contrary, none of the 13 groups observed discussed any aspect on the uncertainty of the data collected.

Protocols of the real experimental task in the triangulation show that in some cases the students had all relevant information of the different areas at hand, yet failed to put them together into a coherent picture. (That is why the design of the model was chosen as a puzzle.) In group 3, for instance, one student commented on the experimental design (which was purposely designed to be very unstable): “The belt [adjusting the curvature] is always slipping off.“ They also realized that the experimental process failed to produce stable results and employed different rules of thumb on the data production and evaluation processes. Yet, when one student suggested repeating one of the measurements for the same shape of the curvature, the other two could not see any reason for it. Moreover, they all predicted the repetition measurement would reproduce the results already obtained during the second check-up, e.g. stating: „I hope it will come out the same!“ At the end, with all information close at hand, yet failing to piece it all together, they were completely puzzled: „Okay – I really wonder why that happened just now.“ – „Me too – beats me.“

Further factors we could determine as influential on the students' practical performance concerned their personal or emotional state of mind. One group, for example, was unable to deepen their rudimental insight into the difficulties of the situation because one of them showed a very low frustration tolerance, causing her partner to become very anxious to present ad hoc solutions without subjecting the thought-provoking impulses to close scrutiny. They thus failed to come to the heart of the problem and discuss the uncertainty involved, as the first student was too easily frustrated and the second too eager to keep her in good spirits. Other important factors mentioned by the students in the follow-up interviews concerned the pressure they felt in a common laboratory task like this one to come up with a proper conclusion after a given (and often too short) time. They admitted that this pressure usually made them adjust their results somewhat to meet the assumed requirements.

CONCLUSIONS AND IMPLICATIONS

Our study concludes that there are many more factors apart from the cognitive ones that influence students' notions on the handling of measurement data and their uncertainty. In our view, those factors are closely related to the way in which we present the experiments in the introductory laboratory and the teaching of physics. The experimental tasks often contain a closed question, they are mostly context-independent and design-free, i.e. the aspired results are often known *a priori* and the tasks commonly do not illustrate a scientific problem but a surgically separated phenomenon. The experimental set-up in most cases is given within the texts and does not allow for or even stimulate any enhancements by the students. As the representation of students' notions by the model of action guiding cognitions show, the links between the areas are often missing, resulting in a poor apprehension of the complex experimental situation in a real laboratory task. Laboratory tasks and especially laboratory introductions to the handling of measurement data and uncertainty should therefore emphasize those links and support students to construct a coherent and complex understanding of the experimental situation. So far, introductions to data analysis in textbooks and in the teaching of physics are most likely to resemble a surgical simplification of the problem and promote rules of thumb that are not rooted in the consideration of the experimental set-up or situation at hand. Given the results of our study, future developments of the physics laboratory should take those factors into account – not only to aim at the transfer of experimental routines, but also at a sound understanding of the connection between different aspects of experimentation. As Buffler *et al.* (2009) point out, these connections are just as relevant when it comes to the understanding of the nature and the handling of measurement data and their uncertainties.

KEY TEACHER'S ROLES IN SUPPORTING THE CO- CONSTRUCTION OF STUDENTS' KNOWLEDGE IN MODELLING-BASED TEACHING CONTEXTS

Rosária Justi[1], Paula Paganini Costa[1] and Nilmara Braga Mozzer[1]

[1]Education Post-graduation Programme, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Abstract: Modelling is a key process in the development of scientific knowledge. In order to conduct a more authentic science education, it is advocated that it should be conducted from a modelling-based perspective. However, the conduction of modelling-based activities in a way that really results in students' learning is not an ordinary task for teachers (who, in general, do neither discuss such a teaching approach in their education process nor experience it as students). In this paper, some data from a modelling-based teaching of solubility which occurred in a regular classroom in Brazil are analysed aiming at discussing the following research question: What are the key teacher's roles in supporting the co-construction of students' knowledge in a modelling-based teaching context? From such a discussion, relevant implications and recommendations for science teachers interested in based their practice in a modelling approach are also proposed.

Keywords: modelling-based teaching, co-construction process, teacher's role.

INTRODUCTION

Modelling in Science Teaching

There has been a general agreement that science education must be closer in terms of process to the practice of science (Gilbert, 2004). As modelling is one of the essential processes in producing, validating, and disseminating scientific knowledge (Gilbert, Boulter, & Elmer, 2000), some science education researchers (for instance, Boulter & Gilbert, 2000; Clement & Rea-Ramirez, 2008) have emphasised the importance of model-based teaching and learning as a way to stimulate scientific understanding. This is so because such a teaching approach fosters students not only to create their own models, but also to assess their models, those produced by their colleagues, and those introduced by the teacher. As an outcome of this process, they can build their knowledge from the establishment of relationships between multiple ideas, as well as understand modelling and its role in the development of scientific knowledge. Therefore, modelling-based teaching also contributes to actively engage students in their learning process, as well as in doing and thinking about science.

In one of the first attempts to shed light on the process of learning via model construction, Clement had proposed a Model Construction Cycle that represents a cyclical process of hypothesis generation, rational and empirical testing, and modification or rejection of a model (Clement, 1989). According to him, such stages were experienced by scientists, but could have relevant implications in science education if the cycle could be used to describe the process that students should experience when learning scientific models. Thus, he claimed the Model Construction Cycle should be used as a basis for designing instructional activities aiming at promoting the learning of scientific models.

In a more recent publication, Clement (2008b) presented a new version of this cycle renamed GEM cycle (model generation, evaluation, and modification). Then, students' learning process was described as constituted by three main aspects: students' initial ideas that base their first model; an evolutionary sequence of models and revisions; and discrepant questions or events that provide scaffolding which enable students to modify their models. This last aspect involves an interaction where the teacher and the students work together to construct and evaluate mental models of a target concept, which Clement named *teacher-student co-construction*.

By analysing what philosophers of science say about how scientific knowledge develops (Nersessian, 1999; Vosniadou, 2002), as well as the work of scientists who have significantly contributed to such a development, Justi and Gilbert (2002) identified some elements and organised them in a diagram (named Model of Modelling) that favours the discussion of how scientists perform the modelling process. It was also inspired by Clement's Model Construction Cycle, but tried to complement it by either introducing new elements or making additional relationships between all their elements explicit. According to it, modelling is comprised of four stages: *elaboration of the initial mental model;* e*xpression of the mental model* by using any of the modes of representation (concrete, visual, verbal, virtual, mathematical, and gestural); *tests of the expressed model* through mental and/or empirical experimentation; and *evaluation of the final consensus model*, that is, the identification of the scope and limitations of the model, which occurs from both contrasting the model with its aims and trying to use it in distinct contexts.

In the last years, our research group have been investigating modelling-based teaching from the 'Model of Modelling' diagram perspective. We have developed teaching sequences comprised of several related activities for a series of chemical topics, which have been applied in regular classes. By participating in these activities, students are involved in all these stages in order to build their knowledge. The use of such activities characterise a socio-interactive constructivist teaching context (Vygotsky, 1986) in which knowledge build occurs from student-student and student-teacher interactions. We recognise that, in specific moments of the process, it is essential that the teacher interact with students in order to favour and foster their engagement in the process. When such an interaction results in students' learning, we say that teacher-student co-construction occurs.

Teachers' action in modelling-based teaching

Some of the main necessary conditions for the occurrence of students' learning are the teacher's own competence in models and modelling, and his/her pedagogical content knowledge (PCK) on this area (Justi & Gilbert, 2002; Justi & van Driel, 2005; Núñez-Oviedo & Clement, 2008). However, previous attempts to characterise such knowledge (Crawford & Cullin, 2004; van Driel & Verloop, 1999) showed that teachers' practices rarely include modelling activities, mainly because they are not competent in this area.

Teachers' PCK related to the conduction of modelling-based activities are different from those involved in ordinary traditional teaching situations. This is so mainly due to the complexity of both the modelling process itself, expressed, for instance, by the dynamic and non-linear relationships in each stage and between different stages, as well as by the conduction of the mediating process.

Some previous studies (Justi, Chamizo, Franco, & Figueirêdo, 2011; Justi & van Driel, 2005) have shown that teacher's PCK on modelling include comprehensive elements like their: general view on modelling-based teaching; knowledge and skills required for producing modelling-based teaching activities; knowledge and skills required for conducting modelling-based activities; general view about how students reason and build their knowledge when participating in modelling-based activities; and knowledge and skills for accessing students' knowledge and skills developed in such a context. Therefore, in order to support teachers' education from this perspective, it is necessary to deeply investigate each of these elements of teacher's PCK.

RESEARCH QUESTION

In this paper, part of the results of an investigation conducted in a modelling-based teaching context is discussed. In particularly, it focuses on one aspect of teachers' knowledge and skills concerning the conduction of modelling-based activities: their actions in favouring knowledge co-construction. The following research question is addressed: What are the key teacher's roles in supporting the co-construction of students' knowledge in a modelling-based teaching context?

METHODOLOGICAL ASPECTS

Context and Sample

A set of modelling-based activities was developed from the Model of Modelling diagram perspective to support the teaching of qualitative aspects concerning solubility to 15-16 year-old students (Mozzer & Justi, 2009). In such a teaching sequence, students are asked to express their mental models by using two modes of representation: concrete mode and analogies. Students perform the activities in groups. During the group discussions, sometimes they also interact with the teacher in order to discuss their doubts or asking his/her questions about the content of their discussions, the codes of representation they used in producing the concrete model, and the aspects of their analogies that has not been clearly expressed. Moreover, after each activity, the teacher conducts a class discussion in which each group presents its ideas/models, justifies them, and answers colleagues' questions about them. It is exactly in the context of such discussions that the co-construction occurs. Therefore, the discussions do not aim at correcting students' models. Rather, they aim at (i) discussing the coherence of the models in the light of both the available information and students' previous knowledge, and (ii) favouring students' own questioning about the proposed models.

Such activities were applied in a regular class comprised of 36 students in the last month of the academic year. They had already studied properties of substances and chemical bonding around 8 months before, but from a traditional approach. As far as our data showed, they had several improper conceptions about both topics and none of them showed any previous acceptable understanding about how a substance dissolves into another. Moreover, they had previous experience with neither modelling-based activities nor investigative experimental activities. In all lessons, students have worked in groups comprised of 5-6 students.

The chemistry teacher guided the whole process. As she had no previous experience with modelling-based teaching, before the starting of the study, the third author met her twice. In such meetings, they discussed about the teaching context, the students' previous ideas related to the topic, the modelling-based teaching from the Model of Modelling diagram perspective, students' drawing of analogies, the relationships between analogies and models, and the conduction of the modelling activities. So, these meetings were essential in order to improve the teacher's understanding on both the modelling-based teaching process and the purpose of our study. The teacher has participated in both the meetings and the lessons with great enthusiasm.

Data Collection

All lessons were video-recorded. The videos focused on the discussion between the students in their original groups and those between the students and the teacher. All the moments when the teacher interacted with a given group of students (for which we were able to record most of the discussions) were transcribed verbatim.

Data analysis

In analysing the transcription, we have identified specific moments in which co-construction occurred. A deeper analysis of such moments made it possible to classify all the teacher's actions in terms of their function in the co-construction process. This was done independently by all authors and some disagreements were discussed until they were solved. Then, such categorisation was used to support the discussion of the research question.

RESULTS

The main teacher's roles in supporting the co-construction of students' knowledge in modelling-based teaching contexts could be organised into five groups of actions. They are presented in no specific order.

Group 1: Organisational actions.

Although they were important in all teaching activities, they have to be emphasised in modelling-based ones because, in such a context, they aimed at favouring the participation of the students in the activities and the expression of their ideas – elements that are essential for the occurrence of co-construction.

For instance, during Activity 2, when one of the groups was producing a model to explain the dissolving of the powder juice in water, one student, who seemed to be a leader in the group, said:

> *I think the juice and the water mixed with each other due to the 'natural' movement of water.* (S1)

Apparently, his colleagues have agreed with him, and continued discussing macroscopic characteristics of the system related to the intensity of the colour. Some minutes later, the teacher, who was following the discussion, asked the whole group:

> *Do you agree with him about the role of the water 'natural' movement?*

Although hesitating, one of them said:

> *There may be something more because… why don't the particles go down in a while?* (S2)

The discussion continued and the teacher continued to provide an incentive for all the students to participate in the discussion, which was essential for encouraging them to express their ideas. This resulted in a significant improvement on their model, as well as in making them think about the relationship between the macro system and a sub-micro model that could explain its behaviour.

Group 2: Actions that favour the expression and discussion of students' codes of representation.

Such actions always occurred when students produced concrete models, and they were motivated by two specific reasons: when the teacher has realised a given code of representation might be associated with students' misconceptions, and when the ideas represented in a model were not clear.

Moreover, when students produced analogical models, the teacher has asked them about the similarities between the compared domains. In some sense, this means to ask about codes of representation because students could explain the structural basis of their representations. For instance, group 2 compared the chalk system with the class in different environments. According to them,

> *It could be the class in the classroom and here, in the laboratory. Here, each group is like a grain of chalk and the groups are not so close to each other. In the classroom the students, like the chalk particles, were closer to each other. Here, in the lab, we are separated in groups, and in each group a given number of students is kept together.*

When explaining the similarities between the two domains, the students were able to clearly express how they were visualizing the sub-microscopic aspects of the system. As the ability to move fluently between the three levels of representation (the macroscopic, the symbolic, and the sub-microscopic ones) is essential to foster a full understanding of chemical phenomena (Gilbert, 2005), questions concerning students' views on the relationships between them tends to favour students' knowledge construction.

Group 3: Actions that favour the expression and discussion of students' previous ideas.

Students' previous ideas are essential to support the building of their initial models and, sometimes, the testing of them. However, very often they do not remember adequate previous ideas, that is, those that may be related to the context in discussion. Other times, it seems that they try to guess without reflecting on their answers. In both cases, teachers' questions about the meaning of such ideas may help students to critically analyse them. For instance, one of the students said both phenomena (water + piece of chalk, and water + powder grape juice) could be explained by the density of the materials. Then, the following dialogue occurred:

T: *Which one is denser: the piece of chalk or the water?*
S5: *The piece of chalk.*
T: *And which one is denser: the powder juice or the water?*
S5: *It should be the powder juice because it sank.*
T: *And what did happen with the piece of chalk?*
S5: *It did not dissolve.*
T: *And with the juice?*
S5: *It dissolved.*
T: *So, how does density explain the phenomena?*
S5: *It doesn't explain. There should be something that is different from one system to another…*

Here, the teachers' questions made the student analyse the phenomena based in his previous ideas. This supported his following conclusions: (i) his ideas were not adequate to explain them, and (ii) the phenomena were not caused by a given characteristic of the material introduced into water, but by a characteristic of the system (that is, something related to the material and the water).

Group 4: Actions that favour the expression and discussion of students' understanding of empirical evidence.

In Activity 3, when students mixed the powder grape juice in water without stirring the system, many of them have showed to be confused by the sequential observations related to the slowly dissolving of the powder juice. Then, the teacher asked them to conduct the experiment again, and questioned each of their expressed observations or comments. This resulted in students using the empirical evidence as sources of information for testing their previous model and producing a new one.

Group 5: Actions that favour the expression and discussion of students' current ideas and models.

Such actions were very common when the teacher interacted with each group and, mainly, when she conducted the final discussions in each activity, that is, when she coordinated the presentation of each group's model to the whole class and the following discussions (when students from different groups argued with each other about their models). In such moments, the teacher has not put the ideas of one student directly against those of other students. On the contrary, she has tried to favour the expression, detail, and justification of each student' ideas. This also resulted in more interactions between the students. From them, students could establish new relationships between their ideas, thus constructing their knowledge.

CONCLUSIONS

In this study, we have identified five groups of teacher's roles that support the co-construction of students' knowledge in a modelling-based teaching context: organisational actions, actions that favour the expression and discussion of students': codes of representation, previous ideas, understanding of empirical evidence, and current ideas and models. This evidences that the teacher's roles go beyond the use of discrepant questions (Rea-Ramirez & Núñez-Oviedo, 2008) or promoting "students to contribute to a discussion with ideas that are contradictory to each other" (Núñez-Oviedo & Clement, 2008, p. 117), as it was proposed in some previous studies. On the contrary, this identification and the analysis of the complexity involved in some situations in which they occur highlight the importance of teachers mediating the learning process, but simultaneously giving students the chance to act in the process. Moreover, teachers should pay special attention in order to identify moments where it is essential to change the focus of a given discussion or to foster students' thinking in a different level (which is particularly important in chemistry teaching because students tend to keep the discussion into the macroscopic level).

Therefore, teachers' educational process should include opportunities for understanding the importance of their actions that can favour the co-construction of students knowledge in modelling-based teaching contexts, developing the knowledge that support such actions, and practicing them. This seems to be a great challenge for science teachers' educators due not only to the complexity of the knowledge characterised in the previous paragraph, but also to the general inexperience of teachers in modelling. However, we believe the characterisation of teachers' actions we presented here can support the proposition of specific activities that may foster the development of teachers' PCK on modelling.

ACKNOWLEDGEMENTS

We would like to thank the Brazilian agencies CNPq, CAPES, and FAPEMIG for the financial help for conducting this study and attending the ESERA Conference.

FORMAL ANALOGIES IN PHYSICS TEACHER EDUCATION

Ricardo Karam[1] *and Elio Carlos Ricardo*[1]
[1]School of Education, University of São Paulo, Brazil

Abstract: Reasoning by similarities, especially the ones associated with formal aspects, is one of the most valuable sources for the development of physical theories. The essential role of formal analogies in science can be highlighted by the fact that several equations for different physical situations have the exact same appearance. Coulomb's law's similarity with Newton's, Maxwell's application of fluid theory to electromagnetism and Hamilton's optical-mechanical analogy are some among many other examples. These cases illustrate the power of mathematics in providing unifying structures for physics. Despite the relevance of the subject, formal analogies are rarely systematically approached in physics education. In order to discuss this issue with pre-service physics teachers, we planned a lecture and designed a questionnaire with the goal of encouraging them to think about some "coincidences" in well-known formulas and to give reasonable justifications. The details of this activity and its main results will be presented. Overall, the outcomes show that although the participants already knew each one of the given formulas, the majority of students were not able to identify deeper similarities between them. The analysis of the students' answers to the questionnaires and to the questions posed during semi-structured interviews allows us to propose a set of categories (levels) to classify the quality of analogy perception.

Keywords: Formal analogies in physics, Analogy perception, Pre-service physics teacher education

IMPORTANCE OF ANALOGIES IN PHYSICS

And I cherish more than anything else the Analogies, my most trustworthy masters (Kepler, quoted in Polya, 1954, p. 12).

Reasoning by similarities (analogy) is one of the greatest sources for the development of physical theories. The essential role of analogies in science can be highlighted by several historical examples: Rutherford's planetary model of the atom, Coulomb's law's similarity with Newton's, Carnot's comparison of heat engines with waterfalls, Thomson's analogy between heat and electricity, Maxwell's application of fluid theory to electromagnetism and Hamilton's optical-mechanical analogy are some among many others. In its essence, analogy is similarity on a more conceptual level, since it is strictly dependent on the intentions of the thinker (Polya, 1954). According to Gentner (2002), the "basic intuition behind analogical reasoning is that when there are substantial parallels across different situations, there are likely to be further parallels" (Gentner, 2002, p. 106). In this sense, analogical arguments can be used to generalize concepts, theories and methods so that they "become applicable to classes of objects which are not of the same kind as those to which they originally apply" (Tzanakis, 1998, p. 69).

Among the broad variety of theoretical frameworks in this field (Vosniadou & Ortony, 1989), we are particularly interested in analogies that are represented mathematically. For that reason, we consider the differentiation between *material* and *formal* analogy proposed by Hesse (1972). According to her, *material analogies* are taken into account when there is a physical similarity between the systems - treating a gas as a set of tiny spheres for example - whereas *formal analogies* occur when the same axiomatic and deductive relations associate both subjects and objects of similar systems, without the necessity of a material similarity between them - e.g., a RLC circuit and a spring-mass system. In this last example two considerably different physical phenomena are represented by the same differential equation and, by focusing on correspondent terms, it is possible to make promising associations such as considering the inductance as the “mass” of the circuit. The distinction between these two types of analogies is not trivial, but Hesse stresses that although two systems may have only formal analogy, the contrary does not seem to be possible since “if there is material analogy, there is presumably some structural similarity that could - at least in principle - be formalized” (Hesse, 1972, p. 355).

Raising attention to the role of formal analogies in physics, Pask (2003) states that “many powerful analogies are those in which the mathematical description component is central” (Pask, 2003, p. 526). As a historical example the author holds that the wave theory success is related to the fact that “Fresnel expressed the analogy between light and other waves in mathematical form and so overcame the mechanism difficulties involved” (p. 529). When it comes to analyzing more recent theories of the contemporary physics, the role of formal analogies becomes even more fundamental. According to Steiner (1998), the only alternative scientists found to overcome the human incapability of reasoning about objects out of our daily life and arrive at the subatomic laws of nature was mathematical analogy. Through an extensive analysis of the cardinal discoveries of contemporary physics, the author emphasizes the methodological change that took place in the last century due to the physicists’ use of *Pythagorean analogies* - “the ones inexpressible in any other language other than pure mathematics” (Steiner, 1998, p. 3). In fact, the unifying character of formal analogies is one of Feynman’s arguments to justify why, despite the enormous amount of information acquired since the beginning of scientific progress, it is actually possible for a physicist to retain a considerably broad knowledge of the physical world:

> *The equations for many different physical situations have exactly the same appearance*. Of course, the symbols may be different but the mathematical form of the equations is the same. This means that having studied one subject, we immediately have a great deal of direct and precise knowledge about the solutions of the equations of another (Feynman, 1964, p. 12-1).

ANALOGICAL REASONING IN PHYSICS EDUCATION

Due to the outlined indispensable role of formal analogies in physics, we strongly believe that they should be approached in physics education. However, one must be aware of the complexity of the theme, since perceiving analogies frequently demands a more expert-like relation to the physical knowledge. In this sense, it is not easy to envisage this approach in secondary school level. Perhaps a promising strategy is to encourage students to think about the reasons for the similarities in some physical formulas they learn. Let us consider the following three equations: $x = x_o + vt$, $v = v_o + at$ and $p_2 = p_1 + \rho gh$. It should not be difficult to bring to light the unifying mathematical structure (final = initial + variation) common to all three equations.

An interesting proposal designed for high-school, which is grounded in formal analogies, is the Karlsruhe Physics Course (Herrmann, 2000). Adopting the intuitive “substance model”, in which substance-like quantities have their balance governed by the differential equation $dX/dt = I_X + \Sigma_X$ (where X is the amount of substance, I_X is a current intensity of X and Σ_X is the production rate of X), this framework enables the establishment of associations between different physical extensive quantities, like electric charge, momentum, entropy and amount of substance. Arguing in favor of a meaningful unified approach to science teaching, the author stresses that “when using the extensive quantities as a basis for structuring the course, one can take advantage of a far-reaching analogy between the various parts of physics" (Herrmann, 2000, p. 52).

STUDY DESIGN: SEARCHING FOR "HIDDEN SIMILARITIES"

Aiming at approaching this theme in physics education, we have conducted a study that involved planning a lecture, designing a questionnaire and conducting semi-structured interviews with the goal of discussing the role of formal analogies with pre-service physics teacher students from the University of São Paulo in Brazil. The questionnaire was designed to encourage them to think about some "coincidences" in well-known physical formulas and demand reasonable explanations. We are mainly interested at the following questions: i) Are the students' capable of recognizing formal analogies? ii) How can the level of this recognition be categorized?

The 4-hour lecture was divided into two parts: the first two hours were dedicated to the discussion of an introductory text (Karam, 2007) on the role of mathematics in physics in which some historical examples and implications for education are presented. Afterwards, the 24 students answered the questionnaire and a final group discussion was coordinated by the lecturer.

In this work we present and describe the analysis of the following question: *Consider the equations $y = gt^2/2$, $K = mv^2/2$, $U_e = kx^2/2$ and $W = CV^2/2$. Comparing their mathematical structure, try to give reasons for the formal similarity between them. Is it possible to establish some correspondence between their terms? Stress not only similarities, but also differences.* This question was part of the questionnaire and was more deeply approached during the semi-structured interviews with four students.

RESULTS: QUALITY OF ANALOGY PERCEPTION

There are several possibilities of establishing analogical relations between the four equations given by the task, from the simple recognition of the integral of a linear relation until the unifying concepts of energy and work. The greater the number of associations perceived the better the quality of the analogy perception. The following table summarizes some possibilities.

	$y = \frac{gt^2}{2}$	$K = \frac{mv^2}{2}$	$U_e = \frac{kx^2}{2}$	$W = \frac{CV^2}{2}$
Constants	g	m	k	C
Linear relations	$v = gt$	$\boldsymbol{P} = m\boldsymbol{v}$	$\boldsymbol{F} = -k\boldsymbol{x}$	$Q = CV$
Infinitesimals	$dy = vdt$	$\boldsymbol{F}d\boldsymbol{x} = \boldsymbol{v}d(m\boldsymbol{v})$	$dU = -\boldsymbol{F}\mathrm{d}x$	$dq = CdV$
Integral $\int_0^x x dx = \frac{x^2}{2}$	$y = \int_0^t gt\, dt$	$K = \int_0^v \boldsymbol{v}.\,d(m\boldsymbol{v})$	$U_e = -\int_0^x -k\boldsymbol{x}\, d\boldsymbol{x}$	$W = \int_0^Q \frac{q}{C} dq$
Work of a force		Moving force	Elastic force	Electric force
Conservative field	Gravitational field		"Elastic" field	Electric field

Table 1: Possible associations between the four equations.

The 24 students who participated in our study performed rather badly on the analogy perception task. The analysis of their answers to the questionnaire, as well as semi-structured interviews conducted with four students, led us to the identification of four levels of analogy perception, which are described and exemplified in the following:

Level I – Superficial recognition of evident similarities (79.2%)

- Superficial similarities are recognized, but **neither physical justifications nor formal deductions are given**.
- Analyzed task: students only notice that all formulas consist of a constant multiplied by a squared variable.
- Transcripts: *"because in all cases we have a constant divided by two and a squared variable"; "the mathematical structure of the equations is similar. All of them have the general form* $y = a.x^2$ *and can be represented by a parabola"*.

Level II – Focus on formal deductions – lack of physical concepts (12.5%)

- The justification is based on formal arguments and mathematical deductions. However, **no physical unifying concept is mentioned** and the physical understanding of the mathematical formalism is deficient.
- Analyzed task: students mention that all formulas come from the integral of a linear function, but don't make correlations with physical concepts like energy, work or field.
- Transcript: *"All formulas can be derived from the integral over the independent variable. E.g.* $y = \int gTdT$*."*

Level III – Focus on physical concepts – lack of formal deductions (Questionnaire: 8.3%)

- Physical concepts are mentioned, qualitative explanations for the similarities are given, but no **mathematical deduction is given**.
- Analyzed task: students mention the relation of some formulas with the physical concepts like energy, work or field, but don't recognize deeper formal similarities.
- Transcript: *"In order to obtain these equations it is necessary to evoke the physical concepts of work and energy. Since these concepts are mathematically represented in similar ways, the equations have the same mathematical structure"*.

Level IV – Coherent combination of physical concepts and formal deductions

- Full comprehension of the analogy. Physical concepts are coherently connected with mathematical deductions. Physical-mathematical understanding.
- Analyzed task: students should mention the relation of some formulas with the physical concepts like energy, work or field and recognize deeper formal similarities (Table 1).
- No student was classified in this level.

CONCLUSIONS

In spite of the relevance of the subject, formal analogies are rarely systematically approached in physics education. In this sense, our preliminary results are actually not surprising. Although the students have already studied each one of these formulas separately, it is likely that they were seldom encouraged to think about these similarities and to find the unifying mathematical structure behind them. Therefore, we strongly believe that an explicit approach of the role of formal analogies with the pre-service physics teachers should enhance the quality of their perception of this valuable reasoning for physics.

Following Feynman's citation, reasoning by formal analogies is an essential physical trait and therefore should be part of the physics teacher training curriculum. Additionally, we believe that it can facilitate students' awareness of the structural role of mathematics in physical thought (Uhden, Karam, Pietrocola & Pospiech, 2011). Thus, it is also related to the introduction of Nature of Science (NOS) discussions in science teachers training courses, which has been widely recommended by the literature (Abd-El-Khalick & Lederman, 2000).

ASSESSMENT OF STUDENTS' CONCEPTS OF MODELS AND MODELING: EMPIRICAL EVALUATION OF A MODEL OF MODEL COMPETENCE

Moritz Krell[1], Annette Upmeier zu Belzen[2], & Dirk Krüger[1]
[1]Freie Universität Berlin, Department of Biology Education
[2] Humboldt Universität zu Berlin, Department of Biology Education

Abstract: Models and the modeling process are important both for scientific inquiry and communication as well as for teaching science. Several studies have described different perspectives of thinking about models. Often, different levels of understanding are either assumed or developed empirically. These levels either can be general, without differences between various perspectives, or they can be specific due to the different perspectives. This means that there are differences in the level of understanding between distinct perspectives. In the present article, a theoretical structure of the understanding and handling of models is presented which is called the model of model competence. In this structure, five perspectives are described, each with three levels with an increasing rate of understanding. Forced choice-tasks were used to assess the students' understanding of models and modeling according to the model of model competence (N = 1,180, aged 13-16). The data was used to address the issue of levels of understanding and handling models. The results indicate that there are no general levels of understanding models and modeling but five distinct perspectives.

Keywords: models and modeling, level of understanding, forced choice-tasks

INTRODUCTION

The importance of models and the modeling practice for scientific inquiry has been well described. For example, models support the development of scientific theories, they allow for the description and interpretation of data and they are promoting creative insight and imagination (cf. Frigg & Hartmann, 2006). Therefore, models are seen as "effective pedagogical tools" (Halloun, 2007, p. 653) for teaching scientific literacy. Because of these advantages, Harrison and Treagust (2000) point out that models are central for teaching and learning science.

The facilitation of a competent understanding and handling of models needs an elaboration of the perspectives that are related to the understanding of models and modeling. Due to diagnostic reasons, it is helpful to describe levels with an increasing grade of competence, too (cf. Hartig, Klieme, & Leutner, 2008). However, it is not clearly investigated whether such levels should be seen as general or as specific to the respective perspectives (cf. Grosslight, Unger, Jay, & Smith, 1991; Justi & Gilbert, 2003; Crawford & Cullin, 2005; Terzer, Krell, Krüger, & Upmeier zu Belzen 2011). In the following, the levels are called *general* when the level of understanding is equal in all perspectives. In this case, there is an understanding of models and modeling "as a whole" (Grosslight et al., 1991, p. 817) and the perspectives are not empirically distinguishable. If the level of understanding differs across distinct perspectives, it can be called *specific* (to the perspectives). In the present article, a theoretical structure of the understanding and handling of models developed by Upmeier zu Belzen and Krüger (2010) is presented which is called the model of model competence. In this structure, five perspectives are described, each with three levels with an increasing rate of understanding. Forced choice-tasks were used to assess the students' understanding of models and modeling according to the model of model competence. The data was analyzed to address the issue of general levels of understanding and handling models. Talking in terms of school practice, this can be used to decide whether to reflect on different perspectives separately or to discuss models and the modeling process as a whole (cf. Justi & Gilbert, 2003).

THEORETICAL BACKGROUND

A Model of Model Competence for Biology Education

Primarily based on the studies of Grosslight et al. (1991), Justi and Gilbert (2003) as well as Crawford and Cullin (2005), Upmeier zu Belzen and Krüger (2010) worked out a theoretical structure in which two broad perspectives (dimensions) of the understanding and handling of models are described (Table 1): knowledge about models and the modeling process (modeling). Whereas the first dimension is subdivided in to the two aspects nature of models and multiple models, the second dimension entails the aspects purpose of models, testing models and changing models. Each aspect is further divided into three levels of understanding based on the concept of model described by Mahr (2009). The author underlines that the identity of something as a model depends on two "constructive relationships" (p. 371): an object is a model as long as it is a model of something (creation of the model) and a model for something (application of the model). Mahr also distinguishes between the model object which can have different modes of representation such as concrete material, visual, or verbal (cf. Boulter & Buckley, 2000) and the model which is "purely mental" (Mahr, 2009, p. 371). Thus, it is possible to understand a model only as a model object without recognizing the connection with the corresponding mental model. This concept of a model was used by Upmeier zu Belzen and Krüger (2010) to develop the three levels of understanding in the model of model competence (Table 1). However, the theoretical structure has not been evaluated empirically yet.

Table 1: A model of model competence (Upmeier zu Belzen & Krüger, 2010).

	Level 1	**Level 2**	**Level 3**
Knowledge about models			
Nature of models	Replication of the original	Idealized representation of the original	Theoretical reconstruction of the original
Multiple models	Different model objects	Different foci on the original	Different hypotheses about the original
Modeling			
Purpose of models	Describing the original	Explaining the original	Predicting something about the original
Testing models	Testing the model object	Parallelize the model and the original	Testing hypotheses about the original
Changing models	Correcting defects of the model object	Revise due to new insights	Revise due to the falsification of hypotheses about the original

Levels of Understanding Models and Modeling: General or Specific?

There are several studies in which the students' (e.g. Grosslight et al., 1991; Grünkorn, Upmeier zu Belzen, & Krüger, in press; Treagust, Chittleborough, & Mamiala, 2004) or the teachers' (e.g. Justi & Gilbert, 2003; Crawford & Cullin, 2004, 2005) understanding of models and modeling is investigated. In the following, three of these are introduced which address the levels of understanding.

One of the first studies about the understanding of models is presented by Grosslight et al. (1991). According to the authors there are mainly five different perspectives (called aspects) in the understanding of models and modeling (kinds of models, purpose of models, designing and creating models, changing models and multiple models). Furthermore, the authors were able to describe three "general levels of thinking about models" which describe the "understandings and conceptions of models […] as a whole" (p. 817). Justi and Gilbert (2003) asked teachers about models and worked out seven aspects which are similar but not identical to the ones described above: nature of models, use of models, entities of which the models are composed, uniqueness of models, stability over time, making predictions and accreditation of models. Justi and Gilbert (2003) explicitly address the question of general levels in their analysis and conclude that "data provide no support for the notion of 'level' in the teachers' understanding of the notion of 'model'" (p. 1381). In fact, most of the interviewed teachers show a complex pattern of understanding which varies across the different aspects (Justi & Gilbert, 2003). A third study which deals with levels of understanding models and modeling is presented by Crawford and Cullin (2004, 2005) who interviewed prospective teachers. The authors report five dimensions which are similar to the aspects described by Grosslight et al. (1991): purpose of models, designing and creating models, changing a model, multiple models and validating and testing models. In addition, the authors assumed four general levels of understanding: limited, pre-scientific, emerging scientific and scientific. Although Crawford and Cullin (2005) were able to report a shift in the teachers' understanding, their subjects "tenaciously held on to some scientifically uninformed views" (p. 318).

In sum, these studies give an ambiguous answer to the question whether there are general levels in the understanding of models and modeling or not. Whereas Grosslight et al. (1991) report general levels, both Justi and Gilbert (2003) and Crawford and Cullin (2004, 2005) are not able to identify general levels of understanding across the different aspects. In other words, it is not clearly investigated whether there is an understanding of models and modeling as a whole or if the level of understanding varies between different distinct perspectives. The present article addresses this issue related to a theoretically developed structure of understanding and handling models which is called the model of model competence (Table 1).

RESEARCH QUESTION AND HYPOTHESES

The research question of the study is related to the empirical evaluation of the model of model competence: In what sense are the three levels of understanding general or specific to the respective aspect? Three alternative hypotheses (H1, H2, H3) can be deduced from the theory:

H1: The three levels are general. The level of understanding does not vary between the different aspects.

H2: The three levels are partly general. The level of understanding does not vary within the two dimensions knowledge about models and modeling but does vary between these two dimensions.

H3: The three levels are specific due to the five aspects nature of models, multiple models, purpose of models, testing models and changing models. The level of understanding varies across all these aspects.

METHODS

Data Collection

On the basis of the model of model competence, forced choice-tasks were developed (Krell & Krüger, 2010). In each task, a concrete model is presented and the respondent has to rank the three levels of the relevant aspect according to his or her own understanding of the shown model. The ranking options were generated deductively and are therefore rather abstract and close to the theory (e.g.: *the model looks like the original*). This is why the forced choice-tasks are assessing what Treagust et al. (2004) call a "theoretical understanding" (p. 16) of models and modeling. In the present study, six tasks for each aspect of the model of model competence (30 tasks in total) were used to investigate the students' understanding of models and modeling. A multi-matrix-booklet-design was conceptualized to keep the number of tasks for every single student small. The sample consists of 1,180 students at the age of 13-16, currently attending public schools (Gymnasium) in Berlin, Germany.

Data Analysis

The data was analyzed using the partial credit-model, a Rasch model which allows for partial scoring (cf. Yen & Fitzpatrick, 2006). In order to test whether the theoretically described levels are general (H1) or specific in terms of dimensions (H2) or aspects (H3), three different measurement models were specified and evaluated in the software ConQuest (Wu, Adams, & Wilson, 2007).

H1: The one-dimensional (1D) measurement model does not differentiate between the tasks of the five theoretical aspects and therefore postulates three general levels of understanding and handling models.

H2: The two-dimensional (2D) measurement model subsumes the tasks of the aspects nature of models and multiple models on the one hand and the aspects purpose of, testing and changing models on the other hand.

H3: The five-dimensional (5D) measurement model was analyzed which postulates the independence of the five aspects (but allows correlations between them).

The three measurement models are nested models (cf. Schermelleh-Engel, Moosbrugger, & Müller, 2003) which deduce directly from the structure of the model of model competence ("choose the model first"; Yen & Fitzpatrick, 2006, p. 124) and which are operationalizations of the three hypotheses H1, H2, H3 formulated above. In order to evaluate the goodness of the measurement models, two information indices were computed: the cAIC and the ssaBIC which are variant forms of the AIC and the BIC. Unlike the AIC, the cAIC takes the sample size into account and the ssaBIC does not overemphasize the parsimony of the measurement model as strong as the BIC (cf. Burnham & Anderson, 2004). The cAIC and the ssaBIC can be used to compare the goodness of different measurement models. When doing this, the smallest value of each index indicates the relatively best fitting model (cf. Kang, Cohen, & Sung, 2009). To test whether the differences between the fit of nested measurement models are significant, one can additionally perform a chi square difference test (cf. Schermelleh-Engel et al., 2003).

FINDINGS

Table 2 shows the information indices for the three measurement models. The results show that in both cases the 5D measurement model describes the data (relatively) best. The chi square difference test shows that the differences between the fit of the three measurement models are significant (Table 3). This is an additional argument for the 5D measurement model. If the differences had not been significant, one should have preferred the most parsimonious model which is the 1D model in the present case (cf. Collins & Lanza, 2010).

Table 2: The values of the cAIC and the ssaBIC for the three measurement models (1D, 2D, 5D).

	cAIC	ssaBIC
1D	13,355.56	13,426.29
2D	13,325.86	13,392.15
5D	13,288.41	13,327.70

Table 3: Results of the chi square difference test. The value of the chi square (x^2), the number of the degrees of freedom (df) and the significance (sig.) are shown.

	x^2	df	sig.
2D - 1D	34.14	2	< 0.001
5D - 2D	64.45	12	< 0.001
5D - 1D	98.59	14	< 0.001

Using the 5D measurement model, fit statistics for the single tasks were computed. The wMNSQ for the overall item parameter is 0.95-1.07, whereas the wMNSQ for the step parameter is 0.88-1.08. Both values indicate a good fit between the tasks and the 5D partial credit measurement model (cf. Bond & Fox, 2001). The findings reported here are in line with the results of a preliminary study with a smaller sample of 901 students (Krell & Krüger, submitted).

DISCUSSION

The findings show that the 5D measurement model describes the data best. In other words, the students' understanding of models and modeling varies between five distinct aspects. For example, the understanding of the aspect purpose of models may be less elaborated than of the aspect testing models (and vice versa). Justi and Gilbert (2003) reported similar results on the basis of their theoretical assumptions. The authors concluded that their interviewees "do not hold coherent ontological and epistemological views" (p. 1382). According to the model of model competence (Table 1), the theoretically described levels do not seem to be general, too. In this sense, the current outcomes are similar to the results reported by Crawford and Cullin (2005) because the authors assumed a structure with four general levels (limited, pre-scientific, emerging scientific and scientific) but were not able to describe general levels of understanding empirically. Whereas both Justi and Gilbert (2003) and Crawford and Cullin (2005) investigated the teachers' understanding, in the present study students were tested. All in all, the more recent findings (Justi & Gilbert, 2003; Crawford & Cullin, 2005; the present study) suggest not to think about the understanding of models and modeling as a whole but to differentiate between distinct aspects.

Regarding the features of the forced choice-tasks, it can be said that they measure an abstract and therefore a more theoretical understanding of models and modeling. Treagust et al. (2004) assessed the students' understanding of models in a similar way and also analyzed lessons in which the students had to handle models concretely. From their findings the authors conclude that a "theoretical understanding of the scientific model is not necessarily related to practical applications of the teaching model" (p. 16). Similarly, Terzer et al. (2011) show that the students' understanding of models and modeling is not the same when being asked on an abstract level (forced choice-tasks) and on a concrete level (multiple choice-tasks developed by Terzer). When assessing the students' concrete understanding of models and modeling, the level of understanding seems to be general (Terzer et al., 2011). The different findings of Grosslight et al. (1991) on the one hand and Justi and Gilbert (2003) as well as Crawford and Cullin (2004, 2005) on the other hand could depend on their slightly different theoretical assumptions (i.e. the different aspects/dimensions). But the forced choice-tasks and the multiple choice-tasks were both developed on the basis of the model of model competence

(Table 1). This strongly supports the findings of Treagust et al. (2004) who report differences between the students' theoretical and practical understanding of models.

PROSPECT

Talking in terms of school practice, the absence of general levels of understanding could indicate a lack in the students' understanding of scientific models and the modeling process in science because an elaborated understanding of models and modeling means to understand all aspects in a sound manner (Justi & Gilbert, 2003). Therefore, teachers should reflect on all the five aspects explicitly (cf. Justi & Gilbert, 2003; Fleige, Seegers, Upmeier zu Belzen, & Krüger, in press).

The differences between the results of the abstract and the concrete operationalizations have to be investigated further (Terzer et al., 2011). So far, the data of both kinds of operationalization have been analyzed separately. Therefore, the next step will be a common analysis of the data to work out direct correlations between the students' abstract and concrete understanding of models and modeling. Doing this, one should find out whether there is a more elaborated theoretical understanding as it is reported by Treagust et al. (2004). In addition, the model of model competence is evaluated using open ended (Grünkorn et al., in press) and hands on-tasks as well (Hänsch & Upmeier zu Belzen, 2011). Looking at the results of the forced choice-tasks in particular, further analysis will focus on the closer description of the students' theoretical understanding of models and modeling. For this purpose, a latent class-analysis (Collins & Lanza, 2010) will be conducted in order to describe several distinct patterns of understanding.

Abstract: A large sample of young science students from several countries has been surveyed to assess their understanding of the nature of science. Each student anonymously answered 15 questions, which involve scoring one hundred sentences that are scaled into a set of attitudinal indices. The global results show an overall neutral (grand mean score around zero) students' understanding, though the detailed examination of indices identifies many differences across countries and positive or negative profiles across issues. The diagnosis that emerges from the data is quite complex, as appropriate beliefs coexist with some inappropriate beliefs within any country. Further, each country's profile allows delineating its specific achievement in relation to nature of science understanding. The results suggest the general need to improve the quality of science teaching on nature of science issues, and especially in those countries whose profile tend to be lower than others. The implications of the methodology and the results for the research, for teaching science, and for teacher training on the nature of science and technology issues are discussed.

Keywords: nature of science, science-technology-society, evaluation of conceptions, student conceptions, trans-national comparison.

Research Project SEJ2007-67090/EDUC funded by a grant of the Ministry of Education (Spain).

BACKGROUND, FRAMEWORK, AND PURPOSE

Science education scholars consider today the nature of science an essential educational goal, and a basic component of the scientific and technological literacy for all, and yet an innovative element of science education, which adds some difficulty to its teaching (Millar & Osborne, 1998).

PISA (OECD, 2010) defines scientific literacy as an individual's scientific knowledge, and the use of that knowledge, to identify scientific issues, acquire new knowledge, explain scientific phenomena and draw evidence-based conclusions about science-related issues; their understanding of the characteristic features of science as a form of human knowledge and enquiry; their awareness of how science and technology shape our material, intellectual and cultural environments; and their willingness to engage in science-related issues, and with the ideas of science, as a reflective citizen.

Summing up, PISA's scientific literacy is made up of knowledge "of" science and knowledge "about" science; the former is the cognitive knowledge of the features, theories and laws that rule the physical, earth and space, living, and technology systems; the latter involves the understanding of science and technology as a form of human knowledge and enquiry, their attitudinal awareness of how science and technology shape our material, intellectual and cultural environments, and their attitudinal willingness to engage, as a reflective citizen, with the ideas of science, and in science-related issues. It seems clear that PISA literacy component involves knowledge, process and attitudinal components about science and technology, designing on its own the nature of science (and technology) (hereinafter, NoS).

Since the early 70s, the empirical research shows repeatedly and consistently that the students do not have a proper understanding of NoS. The students often hold traditional, positivist (logical empiricist), and idealistic views of S&T, which are close to the list of myths on science (McComas, 1996), or contrary to the list of consensuses on NoS (Bartholomew, Osborne & Ratcliffe, 2004). They do not distinguish between science and technology and the current relationships among science, technology and society (STS), do not understand the role of the scientific method, theories and hypotheses, models, creativity and tentativeness in the validation of scientific knowledge (for instance, Lederman, 2007).

RATIONALE

The diagnostic studies of students' NoS understanding have been scarcely conducted in Latin contexts and using big research samples. This paper examines the science students' NoS beliefs from a large sample of young students, who are running their last year in high school (grade 12) or their first year in college, in the framework of an international cooperative investigation (Iberian-American Project of Evaluation of Attitudes Related to Science, Technology and Society, Spanish acronym PIEARCTS) across seven Iberian-American Spanish and Portuguese-speaking countries (Vázquez, Manassero, & Bennassar, 2009). The sample of PIEARCTS consists of several layers:

i) Young students, who begin their college or finish their high-school (17 to 19 years old),

ii) Veteran students in their last year of college, master or just graduate (22 years and older),

iii) In-service teachers of all educational levels.

The new PIEARCTS methodology allows the use of inferential statistics (ANOVAs) to hypothesis testing, for instance, to compare countries or groups of students. The research tries to answer the following questions: Which are the global strengths and weaknesses of NoS understanding of the Iberian students'? Are there differences among countries in students' NoS understanding?

METHODS

The main contribution of this paper is the presentation of a new instrument, scoring method, and quantitative methodology to assess NoS conceptions that allow implementing easy and reliable applications to large representative samples, using inferential statistics to check out differences between groups or setting up cut-off points for deepening the qualitative analyses of the quantitative data.

Sample

The participants are 4,533 young students engaged in the last high-school year or the first college year (most of them about 17 to 19 year-old) and have already made a choice for school science. The sample approximately splits in equal halves by sex (53% men) and by the two questionnaire forms (1 or 2) that answered each student (Form 1, 52%).

Instrument

The participants' NoS conceptions are assessed through a paper and pencil multiple-choice items, which allow easy and reliable applications to large representative samples, due to a new methodology and model design. Each item poses an issue, using a common and simple non-technical language style; a variable number of sentences, each labelled with a letter A, B, C…, follow the stem text. Each sentence states a particular reason that explains a position (belief) on the stem issue. Each item is identified by a five-digit number: the first digit signifies the dimension, and the remaining digits represent themes and sub themes; the five digits plus a letter identifies the items' sentence variables (Vázquez, Manassero & Acevedo, 2006).

The PIEARCTS research team consensually selected 30 items that are allocated into two 15-item paper and pencil research booklets (F1 and F2) from the Questionnaire of Opinions on Science, Technology and Society (Spanish acronym, COCTS). The COCTS is an adaptation into Spanish language and culture of the VOSTS and TBA-STS empirically developed items (Aikenhead & Ryan, 1992; Rubba, Schoneweg & Harkness, 1996), which form a pool of 100 multiple-choice items that inherits the credit of VOSTS and TBA-STS, as one of the best paper and pencil instruments to evaluate NoS&T beliefs (the empirical development of items warrants the item validity). The 30 items contain 200 sentences and cover the dimensions displayed in table 1.

Table 1. Dimensions of the general structure of the issues and labels of the 30 questions included in the two questionnaire forms (Form 1 and Form 2). Note the correspondence between each dimension and the first number of the question label; a short description of the question content (sub themes) follows each key number.

Dimensions	Form 1 Items (key / issue)	Form 2 Items (key / issue)
a) Definition of S&T	F1_10111 science	F2_10211 technology

		F2_91011 epistemological status

Procedures

The respondents rate their agreement (1, total disagreement; 9, total agreement) on each item sentence. These scores are scaled into quantitative indices (-1, +1), whose meaning is invariant across all sentences: the higher (lower) the index score, the higher (lower) the respondent's opinion fitness with the current knowledge from history, philosophy and sociology of S&T (Vázquez & Manassero, 1999; Vázquez et al. 2006). Averaging the sentence indices within each item, four new indices are produced: three indices for the three groups of sentences (categories) and one global index for the whole item. Thus, this scheme describes the student's thinking on NoS through over one hundred and fifty invariant indices (sentence, category and item indices).

The indices allow the use of inferential statistics for hypothesis testing, which can be applied to compare countries or groups, or to set up cutting points for identifying the strengths (highest positive), weaknesses (lowest negative), and neutral beliefs (Vázquez, Manassero & Acevedo, 2006). The criteria to achieve relevance are the statistical significance ($p < .001$), and the effect size, or the differences expressed in standard deviation units ($d > .30$).

RESULTS

The results are expressed through the global item index (weighted average of the sentences through categories) for the 30 applied items in the two booklet forms; the results are analyzed according to the different places (two countries contribute with two places each) where the instruments were applied (each labelled by a letter and a number to preserve confidentiality).

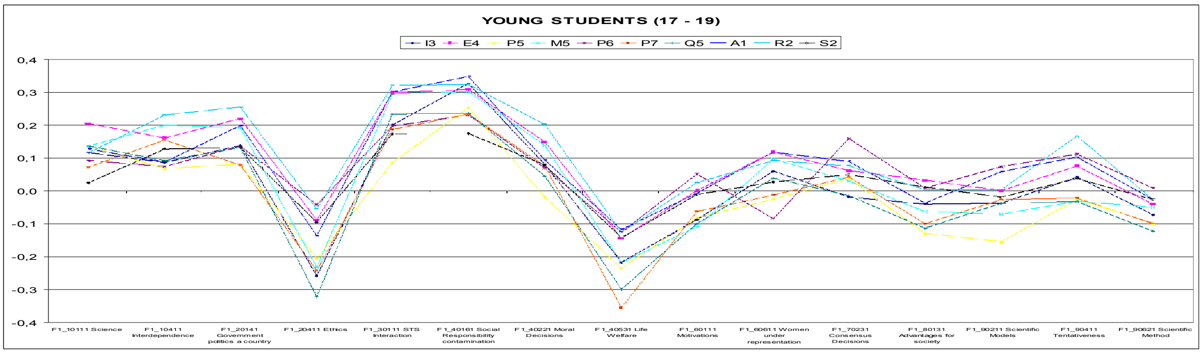

Figure 1. Overall mean results for the 15 items of F1 booklet items across all the places.

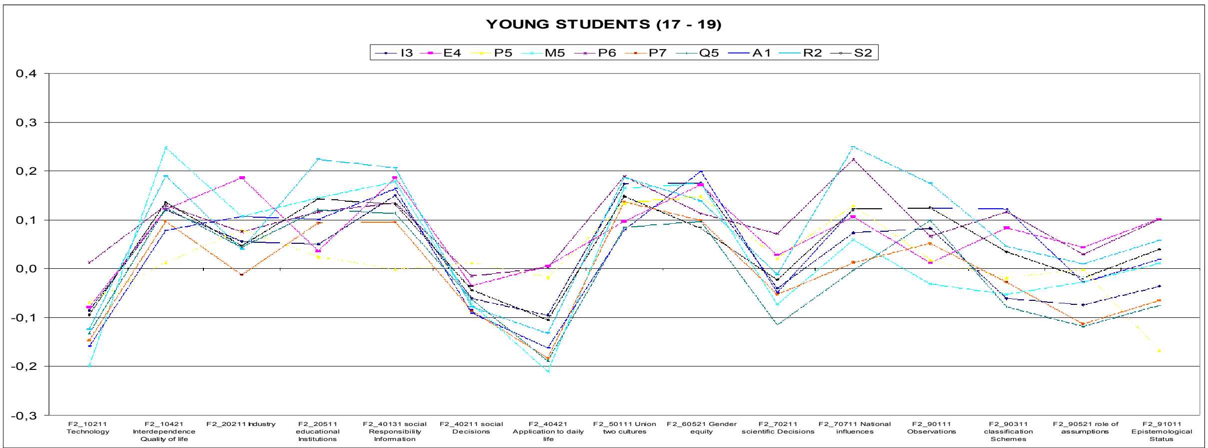

Figure 2. Overall mean results for the 15 items of F2 booklet items across all the places.

Overall, the results show a broad similar evolution across items for the different places; thus, the highest positive (strengths) or lowest negative (weaknesses) scores for the issues are approximately the same for all places. They are selected by the relevant effect size criterion: mean indices higher or lower than one third of a mean standard deviation with respect to the overall mean of the place, though the differences between countries in some items is so high that the strengths and weaknesses are selected on the global average.

The sorted list of F1 and F2 items, which represent students' strengths, is the following: F1_30111 STS Interaction, F1_40161 Social Responsibility contamination, F2_50111 Union two cultures (lower than those of F1), and F2_60521 Gender equity (lower than those of F1).

The list of items, which represent students' weaknesses, is the following: F1_20411 Ethics F1_40531 Life Welfare, F2_10211 Technology, and F2_40421 Application to daily life.

The second feature showed in the figures are some marked differences in NoS understanding between countries and sites, as some sites are getting better and worst achievements than others, and some items display big differences among sites. For instance, sites A1, R2 and E4 display overall top averages along the items, while sites S2 and P7 have got bottom averages.

Further, many items set up big differences among sites, as most of the items exhibit differences greater than .10 (d > .30) between their top and bottom sites, although these relevant differences display somewhat different homogeneity among sites. Just three items exhibit the lowest differences among the sites, which hardly get the relevance criterion (d > .30): F2_40131 social responsibility information, F2_50111 union two cultures, and F2_60521 gender equity.

Obviously, as PISA rules for science achievement, the noticeable differences in NoS understanding among sites suggest the potential relationships between NoS and the school science curriculum design and implementation, or concerns about the effective presence, treatment, and teaching implementation of NoS issues.

The methodology allows the application of inferential statistics in hypothesis testing, which is applied here to compare the NoS beliefs of young students of E4 site against veteran students and in-service teachers. The overall differences among the three groups are not statistically significant, although a noticeable trend is that young students display poorer NoS understanding (lower scores) than the other two groups (veteran and in-service teachers), which exhibit a quite remarkable equality between them (figures1 and 2).

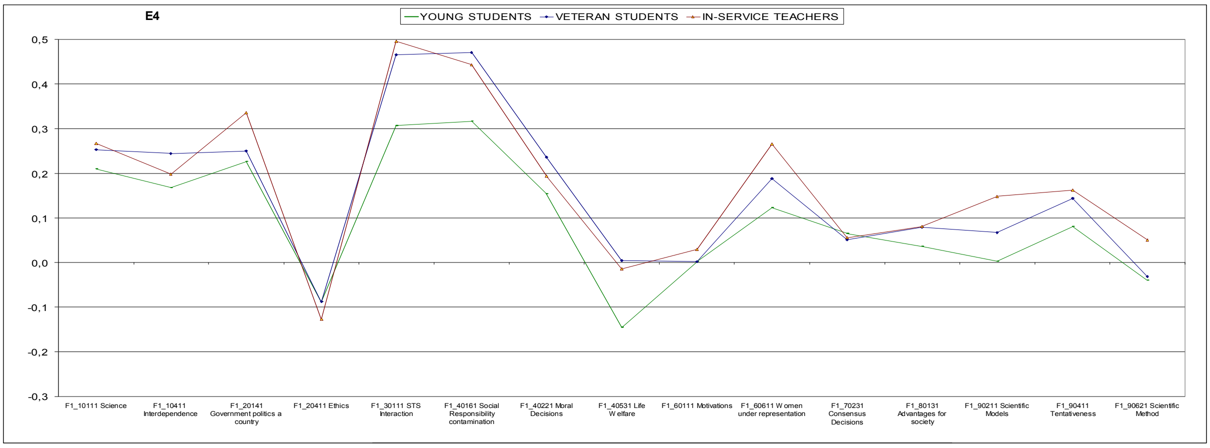

Figure 1. Comparison among young students, veteran students and in-service teachers of the E4 site for the 15 items of F1 booklet items.

When testing the differences among groups along the 30 issues of the two forms, the general trend exhibit some additional nuances, as a few items present significant differences of the young students in relation to the other groups, which means young students score significantly under the other two groups. In F1, the inferiority of the young students in relation to other groups is significant for the item issues F1_30111 STS interaction, F1_40161 social

responsibility on pollution, F1_40531Welfare and standard of living. In F2, young students have scores significantly below the other groups on issues F2_10421 Interdependence, Quality of life, F2_20511 educational institutions, F2_50111 Union of two cultures and F2_90521 true assumptions.
In contrast, the testing of differences also uncovers two issues (F2_40421 Resolution in your daily life and F2_90111 Observations) that attract attention because they provide a counterpoint to the previous dominant trend: young students show higher scores than the other groups, and the differences are relevant for the group of young students.

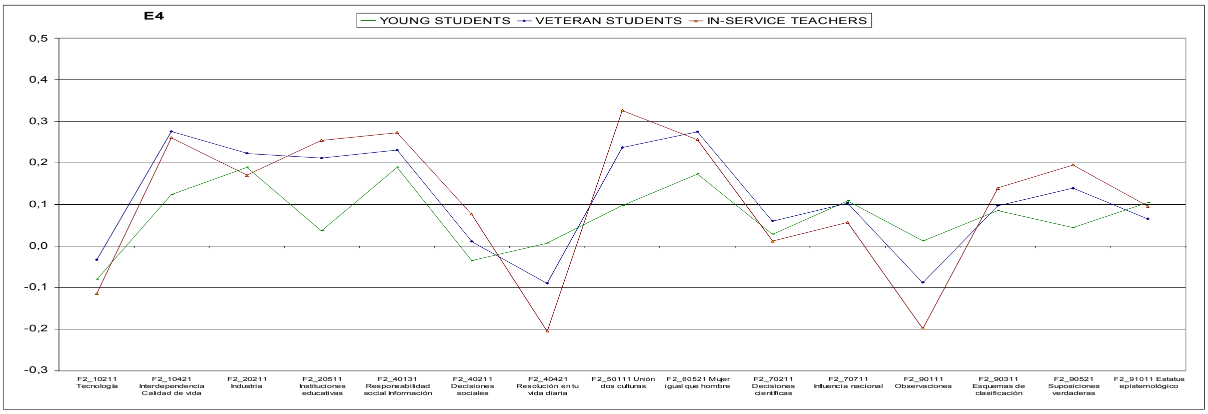

Figure 2. Comparison among young students, veteran students and in-service teachers of the E4 site for the 15 items of F2 booklet items.

CONCLUSIONS AND IMPLICATIONS

The instrument and methodology presented here allows cheap, quick and easy assessments of the NoS, a quality that is specially appreciated for applications to large samples, as is the case presented in this paper. Moreover, the assessment instrument and method fit the requirements recently suggested by Allchin (2011) for appropriately assessing functional NoS understanding: authentic context, well-informed analysis, adaptability to diagnostic, formative or summative evaluation, adaptability to single, mass, local or large-scale comparative use and the respect for relevant stakeholders. Further, the research project PIEARCTS is an example of large-scale applications across seven countries and involving over 16,000 valid answers (Bennássar-Roig, Vázquez-Alonso, Manassero-Mas, García-Carmona, 2010; Manassero et al., 2010).

On the basis of the quantitative use of indices, the study identifies some qualitative features, such as strengthens (conceptions that fit the experts' current knowledge) and weaknesses (conceptions that oppose the experts' current knowledge) on NoS understanding of young students.

The lack of deep differences between young students, veteran students, and in-service teachers, when higher scores would have been expected for science teachers, is a disappointing result, as it points the overall lack of attention to NoS issues in science education. First, the lack of big differences between young and veteran students points out to the relative inefficacy of higher education graduate science programs to adequately teaching NoS. Second, the absence of differences between science veteran students and in-service teachers points out to the inefficacy of teacher pre-service and in-service training to prepare teachers on NoS. Thus, science curriculum design and implementation, and science teacher training have to be redesigned so that the teachers and students' understanding of NoS could be improved.

Most of these strengths and weaknesses are widely shared across countries and the different groups surveyed through the questionnaires (Bennássar-Roig, et al., 2010). As PISA does for science achievement, this study also evidence differences in NoS understanding among countries, which refer back to the development of science education in each country (contents in school curricula, teacher training, practices of teaching, etc.). In fact, the results might be used to highlight national strengths and weaknesses, and develop programs to improve NoS teaching and NoS learning.

THE NATURE OF SCIENCE IN PHYSICS COURSES: PLACE AND ROLE OF THE HISTORY OF SCIENCE

Laurence Maurines[1] *and Daniel Beaufils*[1]
[1]DidaScO, University Paris-Sud 11, France

Abstract: Physics and chemistry programs at the secondary school level in France recommend introducing components of the history of science. Emphasis is placed on a "cultural" dimension, which is poorly defined but essentially refers to elements of epistemological nature. But there is no connection between this implicit epistemological aim of science education and the learning goals specified for each thematic domain: they only concern the scientific concepts and process. Our main issue is to examine the possibility to communicate a more authentic image of the nature of science with the introduction of the history of science. We begin by demonstrating how our historical and epistemological analysis of physics led us to distinguish different aspects of scientific activity that may constitute key points for a didactical transposition and can be chosen as different learning goals. We then show how these goals (e.g. "interactions between scientists" or "science-technology relationships") can generate kits of texts and activities for students that are both appropriate to a given level of instruction and fulfil such a specific epistemological objective. Our innovative approach is based on the nature of investigative situations (with experiments or not): the reading assignment is divided among all students and the synthesis consists in collectively drawing a diagram providing a synoptic visualization of the epistemological objective. Finally we discuss the tensions that our choices created among teachers.

Keywords: nature of science, history of science, secondary level teaching, innovative pedagogical units, teachers

INTRODUCTION

The issue of the nature of science (NoS) is more suggested than explicitly stated in the French science programs at the secondary school level. It may be extrapolated from their introductive components that recommend introducing *an historical perspective*. Emphasis is placed on a "cultural" dimension, which is poorly defined but essentially refers to elements of epistemological nature. But there is no connection between this implicit epistemological issue of science education and the learning goals specified for each thematic domain: they only concern the scientific concepts and process. Moreover, the programs suggest very few examples of activities based on the history of science (HS): most of them are means to learn scientific content and convey a reductive and false image of science. This is the same case for the science textbooks (Beaufils & Maurines, 2008; Guedj, Laubé, & Savaton, 2007). Their historical elements refer to only one person who is most often well known. Discoveries seem to happen immediately and are linked to a specific date; they appear to be animated by a superhuman mind possessed with intuitive genius, arising from an unequivocal idea or a decisive experiment. Besides, many teachers share an outmoded vision of the sciences (empirically inductive and naïvely realistic) and unconsciously convey this stance to their students through the way they teach. Moreover, they are unaware of the epistemological issue of science learning (Robardet & Vérin, 1998; Pélissier, Venturini, & Calmettes, 2007).

This situation, close to the one described abroad by many science education researchers (Höttecke & Silva, 2011; Larochelle & Désautels, 1992; Lederman, 2007; Matthews, 2003; Mathy, 1997) working on NoS led us to begin a research program that examines whether the introduction of HS[1] in teaching can help to address the epistemological issue of scientific education. Our position is unique in France. Almost all other recent work concerned with the use of HS in physics courses (Décamp & de Hosson, 2010; de Hosson & Kaminski, 2007; Guedj, 2005) does not explore this aspect but focuses on the acquisition of scientific concepts; the historical elements introduced in most of these different studies concern controversies over the interpretation of specific phenomena and are minimalized.

The underlying stake of our research is that historical resources and student-centered activities, which offer a heightened sense of the reality of NoS, can provide a broader scientific cultural integration for students and have a positive effect on their relationship with science as an academic discipline. This is a significant societal issue, given students' current disaffection with the branches of basic science. We confer with Solbes and Traver (2003) on that point. Moreover, following Driver, Leach, Millar and Scott (1996), we also believe that the acquisition of a scientific and cultural background allow students to become responsible citizens, capable of understanding and taking action in a world where science and technology occupy a predominant place.

RESEARCH QUESTIONS AND METHODOLOGY

The issue of greater authenticity in representing NoS in physics classes has several main aspects. First, how do we characterize this authenticity and which approach do we choose in order to address the cultural and democratic rationales for including NoS in science teaching? Second, what pedagogical goals can be pursued and can historical examples be found that are compatible with science programs and students' academic level? If so, what historical resources and activities support these objectives and how are they integrated in the traditional teaching focused on science content? Third, how teachers judge these innovative proposals and put them into practice? The area of specialization of our team members led us to explore these questions in the case of physics.

Our work initially consisted of complementary analyses concerning the nature of science and scientific activity, the high school programs, the science textbooks, the students' and teachers' epistemological conceptions and teachers' practices. They led us to 1) discern different characteristics of scientific activity and knowledge that may constitute key points of an authentic image of science upon which didactic goals may be based *a priori* ; 2) identify "historical situations" (e.g. the interpretation of the law of refraction) that could be integrated into physics' curricula. We then created and designed didactic resources and activities for students that were both appropriate to a given level of instruction and fulfilled a specific epistemological objective. Before spreading our pedagogical propositions, we sought to improve them in taking into account teachers' feed-back. We contacted various colleagues who had replied to a first inquiry on their relationship to the use of the history of science in teaching (Beaufils, Maurines, & Chapuis, 2010) and expressed interest in receiving complete pedagogical resources. The information returned to us completed the first synthesis of material that resulted from a session of ongoing teacher training (January 2009). Some results of this stage of our research are given in the last section of this paper.

DESIGN OF INNOVATIVE PEDAGOGICAL UNITS

Epistemological learning goals

In our project, HS is not considered *per se* but as a means to introduce students to 20th century philosophical ideas on science[2]. This is a richer understanding of how science works mainly today, and not in the past, that we expect. Consequently, we sought to identify through the analysis of the history of physics what aspects of physics can be considered as temporal invariables[3]. Since the intersection of the various studies of science is where the most authentic view of science is revealed, we based our analysis on the philosophy, history, psychology and sociology of science[4]. This approach led us to the "consensus view" of the nature of science which comprises a set of aspects widely accepted in standard documents (Project 2061 for example) and philosophy of science (Lederman, 2007).

In our opinion, introducing the history of science highlights episodes of scientific activity of various lengths seen through a series of critical filters relative to the NoS such as show that 1) scientific activity is a nexus of controversy; 2) scientific knowledge follows criteria of internal coherence, simplicity, and strength and has to be confronted with facts based on observation and experiments; 3) a scientist does not work in isolation but within a community that participates in testing established scientific knowledge; 4) there is a relationship between technical questions and the evolution of ideas; 5) etc. We would like to observe first of all that since these goals focus on epistemological aspects, they are independent of conceptual or procedural learning objectives, which therefore can be only secondary, if not completely absent. This position is close to the one presented by Lederman and Abd-El-Khalick (1998) about activities relating to the nature of science.

Historical resources for students and historical investigative situations

Several didactic choices determined the direction of our pedagogical research: elaborating resources and suggesting activities for students beyond simply providing documentary resources for teachers, offering collective activities to students that permit complementary or contradictory interactions, the development of common, shared knowledge, etc. In other words, the choice reflected our attempt to integrate the resource kits with investigative situations which pair texts with experiments or not. With a view to suggesting a wide variety of activities to teachers and pupils, we have developed resource kits based on short documents, designed according to the stated goal. The documents present information in different forms—texts, diagrams, drawings, etc.—which is usually taken from texts written by historians or scientists keen on history but also from primary sources or which we can have written. Our primary objective is to propose students with texts easily to read.

Historical experimental investigative situations

In some of our first proposals (Maurines and Mayrargue, 2005, 2007), the reading of historical texts is coupled with doing an experiment described or inspired by the texts, thereby following the hypothesis that some teachers prefer situations that link texts with experiments, since they might not want to deviate from their preferred conceptual or procedural learning goals. This approach becomes most meaningful when the targeted goal stresses the process of validating a model by confronting its prediction with facts derived from observation or/ and experimentation (e.g. in insert 1). The choice seems artificial, however, and therefore inappropriate in relation to a goal like studying "interactions between scientists." In this type of situation, the risk of drifting off course toward an emphasis on knowledge and methods is especially high. It is fundamentally important to explicit the epistemological dimension during the last phase of the teaching situation. Höttecke et al (2010) whose approach is close to the one proposed here suggest to arrange furniture in the classroom in order to create an "epistemological corner", i.e. a place dedicated to the reflection on the nature of science.

Insert 1: A possible structural outline of an activity combining texts and experiments (Topic: the dispersion of white light through a prism)

Appropriating or/and constructing a problem
- create a conflict by reading texts: compare de Dominis' and Newton's models.
- state hypotheses inspired by the texts: Is white light homogeneous and are colors created uniquely by the action of the prism?

Resolving of the problem
- develop experiments that allow the hypothesis to be tested, revealing its consequences.
- confront expectations with the results of the experiment
- invalidate the model of homogeneous white light

Establishing knowledge
- **scientists test their explanations against facts that result from observation and experiments; they valorize those explanations that allow for a large number of facts to be interpreted simply**.
- white light is heterogeneous and composed of colored light

Historical documentary investigative situations and synthesis diagrams

More recent proposals (Maurines, Beaufils, & Chapuis, 2009) are based on the collective analysis of resource kits designed to examine a specific characteristic of scientific activity: the interactions between scientists, the relationships between technical questions and the evolution of ideas, for instance. Insert 2 presents a possible structural outline of such documentary investigative situation.

Insert 2: A possible structural outline of an investigative situation based on texts

Appropriating or/and constructing a NoS problem:
- integrate the topic into the teacher's learning sequence for the class; highlight questions of a historical nature: *how do we know that...?*
- specify a specific problematic that sets the goal to be achieved

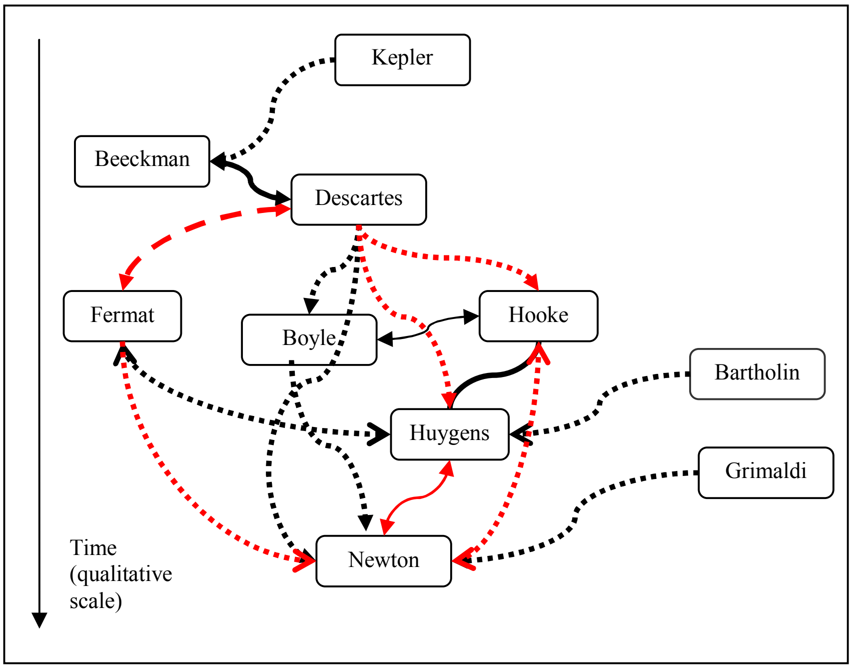
Resolving the problem :
1) Documentary work (as homework or in class, individual or in small groups)
- present documentary resources.
- distribute the documents among the members of the class
- read documents and prepare the lesson in which the synthesis will be done, guided by instructions that specify the type of information to be culled from the text; who, what, how, why, etc. (in relation to the documents and the question).

2) Reaching a synthesis (students will do this collectively based on each class member's contribution)

Establishing knowledge:
- **the teacher generalizes the results that were found by students and shows the connection between how science worked in the past and the present situation**.

The kits are usually composed of about ten interrelated documents, characterized by a "point of entry" directly related to the goal to be achieved: this might take the form of scientists' names, for instance, or technical achievements. Contrary to the stories proposed by Clough (2010), each document gives only some information. The reading assignment of the kit is divided among all members of the class and the collective synthesis is made under the teacher's "guidance". Thus, enough information can be provided to students in order to convey a more realistic image of NoS without discouraging poor readers and requiring too much time. The synthesis that is made in class is supposed to produce a specific type of result: a diagram that provides a synoptic visualization of the information that has been gathered and illustrates the targeted goal. Insert 3 presents an example of such diagram that students could produce. As far as we know, this collective strategy and type of synthesis activity have never been proposed by science educators contrary to the previous one which pairs texts with experiments (Höttecke, Henke, & Riess, 2010).

Insert 3: Example of diagram on the epistemological objective "interactions between scientists" and the topic "laws of refraction"[5]



BY WAY OF CONCLUSION: SOME REMARKS ON THE FIRST FEED-BACKS OBTAINED FROM TEACHERS

The majority of responses given by the sixteenth teachers who answered the questionnaire on the feasibility of our proposal on the topic of refraction and on the epistemological goal "interaction between scientists" indicated that the objective was interesting, stressing the fact that the evolution of science, with its complexity and social dimension, should be demonstrated. Responses were largely positive in favor of presenting this kit at the grade 10 level but some colleagues' expressed reserve and were concerned that the intellectual level of the students would be overly challenged by documentary activities involving reading that was beyond their critical ability. The answers to the questions on the pedagogical organization range from positive feed-back arguing for a simple activity that could be integrated into the complete set of activities students are asked to perform, to negative feed-back, arguing that the texts were too difficult, that the synthesis students were asked to make (a diagram) was too abstract, and that the context was too exclusively cultural, independent of notional learning, requiring highly motivated students. They also argue that they are not trained on the NoS. All this send back to a curriculum issue (conception of science programs and aims which are assigned to them) but also to an issue centred on the teachers (their training and their conception of science teaching, and more fundamentally, of science).

NOTES

[1] Other proposals can be found in Maurines (2010).
[2] Our approach is similar to Aduriz-Bravo's one (2010).
[3] Since the modern period.
[4] We agree with Mc Comas, Clough and Almazroa (1998) on that point.
[5] The arrows are different because they are different types of interactions. Continuous double arrow: direct interaction. Dashed double arrow: epistolary interaction. Dotted single arrow: knowledge of the works. Red double arrow: interaction with controversy. Red single arrow: opposition of points of view.

THEORETICAL MODELS FOR (MESO)CHEMISTRY: PARADIGMATIC FACTS

Cristian Merino[1] *and Mercè Izquierdo*[2]
[1]Instituto de Química. Pontificia Universidad Católica de Valparaíso, Chile
[2]Departameto de Didáctica de las Ciencias Experimentales, Universidad Autónoma de Barcelona, España.

Abstract: We wonder about the meaning that Chemistry can have for those who are learning it without identifying themselves with the academic pursposes of the discipline, because they are unable to, due either to their age or context (school). From this reflection, we propose a modelling orientation for chemistry teaching. We use the "theoretical model" notion from the current cognitive approaches of the philosophy of science, which propose a semantic concept of scientific theory which facilitates the approach between phenomena and the theories that explain them. We developed a chemistry at a "meso" level, which gives a very important function to the atomic theory, but not protagonisim, which belongs to "Chemical Change." The study of the exemplary changes following the rules and the languages of chemistry guides and gives coherence to the lessons, where "Ideal Chemical Facts" are built. The cognitive dimension leads us to identify the coherence between the students' experimental interventions, their abstract representations, and the languages they use to explain what they are doing, what is happening, and why it is happening. Whe identify the modelling process with the progressive fit between these three dimensions of human cognition. The discourse analysis of universitary students from a "chemistry for all" course allow us to identify the relationships the students established between their representations, experimental interventions and the languages they used.

Keywords: Chemistry, Representation, Language

BACKGROUND, RATIONALE AND PURPOSES

Research on chemistry teaching based on models has become increasingly important, due to new educational aims that require the students to be competent in the use of the scientific knowledge to their own reality. This new curricular orientation, in elementary as well as in universitary education, pushes us to urgently desing a new way for teaching chemistry. This research includes diverse fields: the study of experiences or phenomenology (Andersson, 1990); classroom discourse analysis (Mortimer, 1998); pedagogical content knowledge (Shulman, 1986); the "perspectival realism" (Giere, 1988). All of them asked themselves how the "school chemistry activity" (SCA) which makes the students put their cognitive capacities (think, do, and communicate in a coherent way) on trial is built (and developed). In order to do this, it is necessary that the experimental situations they are intervening can be mentally and simbolically represented (Gilbert, de Jong, Justi, & Van Driel, 2002), to create a standpoint for chemical-problem solution. to generate chemical approach to the phenomena. In our modelling process analysis we also apply our theoretical framework (Author & Adúriz-Bravo, 2003) and an epistemological approach as has been explained by Sénsevy (2008) et al (2009). In this paper we wonder how tuned languages, representations and experiments (LER) in a modelling process to acquire (get into) a relevant school chemical knowledge.

Framework

We present the students some carefully-chosen chemical phenomena as "problems" that provide the context and opportunity to introduce the essential and elementary and chemical ideas, which give sense to the problem; it can be solved and related to other problems important to chemistry. We "modelled this phenomenon"[1]: we "colonized" it by applying to it the chemical ideas (laws of chemical change) and by representing it, as far as possible, through atomic theory which will allow to introduce the formula language, basic to communicate "what is happening" when a chemical change takes place. Because of this, a "natural change" becomes a chemical change, that will be a MODEL to identify some others that are similar. The data presented for this communication are taken from the student's discourse regarding a phenomenon: "pyrolysis (carbonization) of wood". This phenomenon, as well as all the rest that will become "Chemical Change Models" has to follow the *"rules of the chemistry play"*:

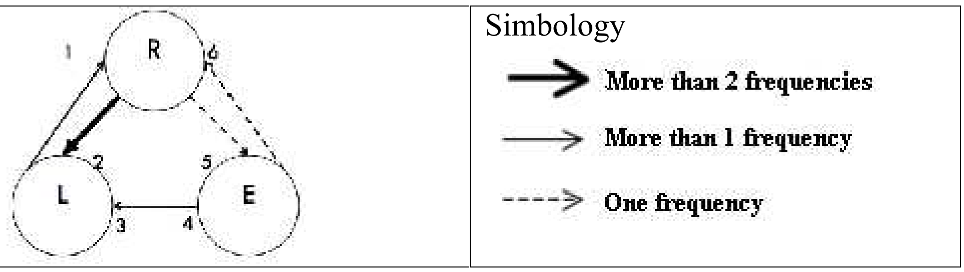
a) Some substances dissappear and others appear.
b) The elements are preserved. The mass is conserved (in atoms, including electrons)
c) The substances react in fixed proportions (chemical equations)
d) Energy is conserved (chemical bond)
e) In the final state, there is no more "chemical potential" available.

METHODS.

We had a video recording of three sessions where the students used models to explain the pyrolysis of wood and answer the teacher's questions. The students worked in three-to-four people groups. The models had been built freely with different materials (play dough, strips of paper, 3D models to represent molecules...). The recordings were transcribed and analyzed identifiying "interactivity segments" and "acting patterns": Inquiry (I), Start (S), Feed-Back (F), Evaluation (E). The dialog was coded in terms of the foreseen transitions; (L↔R; R↔E; E↔L…) and some "transition maps" were made, and then interpreted. The data were gathered from the instrument showed below (tabla 1) and were represented with diagrams (fig. 1)

Paradigm/ Sentences	Complement that enriches the explanation of the sentence	Transition L-E-R	Interpretation
Students' phrases	Elements that provide the context		

Table 1. Transition language-experiment-representation



[1] It is frequent that the models represent scientific entities as the phenomenon interpreted, and not the phenomenon itself, where the entities stem from.

Figure 1. Example diagram

RESULTS

Different diagrams that could be compared with each other (see table 2) as well as with the diagrams from the same student's discurse in different pedagogical situations were obtained. Although only in few situations all the transitions are present, we have been able to prove that in the cases where the modelling process could be applied, this was successfully accomplished (see table 2).

Case	Lorena	Juan	Tomas	Paloma	Maria	Marta
Representation of the transition						
Table 2. Diagrams for six students in the same class session.

CONCLUSIONS AND IMPLICATIONS

We think that choosing the pyrolysis of wood as "paradigmatic fact" was the right decision to make, because it is an everyday phenomenon that can be intervened, that starts and ends, and which also allow to mass. It requires a control (for the wood not to burn) that is available for the students and that allows them to intervene in the process in an autonomous way, and when doing so, they can recognize the combustion process. We think it interesting to have identified in the student's discourse the transitions between their references to the real phenomenon to the representation in the model and to their "giving a name" which gets more scientific as they manage to interpret the change with the entities represented by the model.

We have been able to empower the meaning of the terms: model, paradigmatic fact and representation in our research project about the "chemical chemistry" teaching. He have realized that the relationships between thinking, experimenting, and communicating based on a determined planning that gathers the phenomena in groups or "fields with the same conceptual structure", allow to rebuild "facts of the world" according to the chemical theory, that will become "Theoretical Models" of the chemical theory. What we call "School chemical-change model" gives us the conductive thread to develop the curriculum focusing on the paradigmatic examples from Chemical Change.

STUDENTS' ANALOGICAL REASONING WHEN PARTICIPATING IN MODELLING-BASED TEACHING ACTIVITIES

Nilmara B. Mozzer[1], *Rosária Justi*[1], *& Paula P. Costa*[1]

[1]Education Post-graduation Programme, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Abstract: One of the ways students can express their mental models is by drawing analogies between an already known domain and the domain of the scientific topic they are learning about. The literature stated that analogical reasoning is comprised of some sub-processes but in previous studies we have shown that in regular teaching situations, students do not spontaneously experience all of them, thus resulting in problems in students' learning. In this paper, we have identified evidence of such sub-processes in students' analogical reasoning when they participated in a modelling-based teaching about solubility that occurred in a regular classroom. From them, we discuss the influence of modelling-based teaching conducted in regular classrooms on students' experience all the sub-processes of analogical reasoning.

Keywords: modelling-based teaching, analogical reasoning.

INTRODUCTION

Analogies are relational comparisons between a familiar and an unknown domain (Duit, 1991; Gentner, 1983; Glynn, 1991). Therefore, from drawing an analogy, one expresses a partial representation of an idea. This implies that analogies are models (Duit, 1991).

Although many researchers recognise its importance, there is no general agreement in cognitive science literature (for instance, Gentner, 1989; Holyoak & Thagard, 1997; Vosniadou & Ortony, 1989) about how the analogical reasoning process occurs. In attempting to understand analogical reasoning, this process has been decomposed into basic sub-processes: (i) *access*: one or more relevant known domains should be accessed; (ii) *mapping*: one familiar domain is mapped on to the target domain by identifying systematic correspondences between them; (iii) *elaboration of inferences* about the target, favouring domain understanding; (iv) *evaluation of the match*, followed by changes in the inferences in order to fit them with special aspects of the target; and, sometimes (v) *generalisation*: extension of inferences to all cases in which they could be applied.

The drawing of analogies is a daily action of human reasoning. However, the situation is different in the context of science classrooms where, in general, teachers present analogies to students and ask them only to understand the mapping relationship. In the science education area, few studies have been conducted on analogical reasoning in which students draw, use, and modify their own analogies (Cosgrove & Schaverien, 1996; Kaufman, Patel, & Magder, 1996; Pittman, 1999; Wong, 1993). In our previous study (Mozzer & Justi, 2010), we analysed how students reason analogically when they are asked to draw analogies for a scientific target domain they are currently learning about. We showed that, in general, students have no difficulties in performing both the access and the mapping sub-processes. On the other hand, they do not perform the other sub-processes (evaluation of the match, proposition of inferences, and generalization) unless they have been specifically asked to do so. As a consequence, students may either develop alternative conceptions from improper matches between non comparable relations and/or attributes of both domains, or misuse the analogy in other contexts. This implies that if students' drawing of their our analogies is to be part of teaching activities, teachers must foster them to accomplish all the analogical reasoning sub-processes. This would favour their involvement in those sub-processes that are not spontaneous for them.

As analogies are models, one of the possible ways to involve students in all analogical sub-processes would be by engaging students in modelling-based teaching activities. According to Justi and Gilbert (2002), modelling is a dynamic and non-linear process comprised of four main complex stages: the *production* of a mental model; the *expression* of that model in any mode of representation; the *tests* of the model; and the *assessment* of the resulted model, that is, the consideration of the scope and limitations of the model.

RESEARCH QUESTION

When students participate in modelling-based activities produced and conducted from the Justi and Guilbert's perspective, they experience all these stages. As the skills involved in such experiences are, in some way, similar to those involved in analogical reasoning, we have supposed that modelling-based teaching could contribute to students' accomplishment in performing all the analogical reasoning sub-processes. Assuming this hypothesis, in this paper we discuss the following question: How can modelling-based teaching conducted in regular classrooms contribute to students' experience all the sub-processes of analogical reasoning?

METHODOLOGICAL ISSUES

Context and sample

A series of modelling-based activities was developed to support the teaching of solubility to 15-16 year-old students (Activities 1-4 in figure 1). Such activities aimed at favouring students' creation of a qualitative model that explained sub-microscopic aspects involved in dissolving. Such a teaching sequence is similar to other teaching sequences we had developed in the sense that the activities were elaborated in such a way as to favour students involvement in all stages of the modelling process. On the other hand, this teaching sequence has a unique characteristic: students are required to express their models both in a concrete mode and by drawing analogies. This is justified by our intent to investigate students' generation of analogies in a modelling context.

These teaching activities were applied in a regular class comprised of 36 students (15-16 years old) in the last month of the academic year. They had already studied properties of substances and chemical bonding around 8 months before, but from a traditional approach. As far as our data showed, initially they had several improper conceptions about both topics and none of them showed an acceptable understanding about how a substance dissolves into another. Moreover, they had previous experience with neither modelling-based activities, drawing of analogies in science classes, nor investigative experimental activities. On account of this, before the modelling-based activities, students participated in an extra activity based on the Teaching-with-Analogy (TWA) model (Glynn, 1991) involving the analogy between the solar system and the Bohr atomic model (Activity 0 in Figure 1). It aimed at facilitating students' understanding about the meaning of analogies in science.

Activity	Brief description
0	Identification of the relevant characteristics of both the Bohr atomic model and the solar system. Mapping the similarities between both domains, with special emphasis on the relational mappings. Identification of the differences between both domains.
1	Presentation of two systems (water + piece of chalk and water + powder grape

	juice) that have different behaviour in terms of the solubility of the solid material in water. Elaboration of prediction about what is going to happen in each system when their components were mixed. Conduction of the empirical experiments and registration of the observations. Discussion about possible differences between previous predictions and actual observations.
2	Elaboration of a model to explain the observed phenomena at the sub-microscopic level and expression of such model in a concrete mode of representation. Drawing of analogies to explain the represented phenomena. Identification of the similarities and differences between the aspects compared.
3	Observation of new behaviour of one of the systems (mix of powder grape juice in water without stirring the system). Attempt to use the previous analogies in order to explain the new behaviour of this system. If necessary, modification or rejection, followed by new elaboration, of previous analogies and/or concrete models.
4	Extension of possible analogical inferences to other situations related to the modelled phenomenon.

Figure 1. Brief description of the teaching activities.

Throughout all lessons, students have worked in groups comprised of 5-6 students. The teacher guided the whole process. As the chemistry teacher had no previous experience with modelling-based teaching, before the starting of the study, the first author met her twice. In such meetings, they discussed about the teaching context, the students' previous ideas related to the topic, the modelling-based teaching, students' drawing of analogies, the relationships between analogies and models, and the conduction of the modelling activities. So, these meetings were essential in order to improve the teacher's understanding on both the modelling-based teaching process and the purpose of our study. The teacher has participated in both the meetings and the lessons with great enthusiasm.

During the lessons, she has tried to favour students' discussions by stimulating them to critically analyse, to modify, and, sometimes, to reject their analogies and other models. She has also asked them: to explain their choices about modes of representation, as well as the meaning of particular codes of representation; and to explain their ideas, to think about the coherence of the ideas expressed in their concrete models and analogies. Finally, she also tried to produce generative questions – those that "cannot be answered on the basis of stored information but require the genuine solution of a new problems" (Vosniadou, 2002, p. 358) in order to favour students' rethinking about specific aspects of their models.

Data gathering and analysis

All five lessons were video-recorded by using two cameras. The videos focused on the discussion between the students in their original groups and those between the students and the teacher. Additionally, the discussions in each of the groups were audio recorded, the written material produced by the students was collected, and the concrete models they produced were photographed.

From the integration of such data, we produced case studies for each of the students' groups. The most complete of such case studies (that is, the one that include most of the moments in which students were producing and discussing their concrete models and analogies) was from a group comprised of six students. Such a case study was analysed aimed at making it evident the elements of the modelling activities that had contributed to students' experiencing of all the analogical reasoning sub-processes, and to the development of their knowledge about the dissolving process.

CONCLUSIONS AND IMPLICATIONS

From the analysis of our results (not presented here due to the limitation of space), we identify the elements of the modelling-based teaching that may have contributed to students experiencing all the sub-processes of the analogical reasoning. They are presented in figure 2. From them, we draw our conclusions and present some implications of this study.

Sub-process of analogical reasoning	Action in the modelling-based teaching	Modelling stage	Activity
Access and mapping	▪ After the observation of each phenomenon, request to produce a mental model, and to express it as concrete models and as analogies that could explain them. ▪ When necessary, request explanations about the mapping between the compared domains.	Production of mental model. Expression of the model.	1 2 3
Evaluation of the match	▪ Opportunity for students to observe new empirical evidence. ▪ Explicit request (from both the activities and the teacher) to express the similarities and differences between the compared domains. ▪ Explicit request, from the teacher, to analyse their comparisons for the new knowledge built during the class discussions.	Tests of the model.	3
Proposition of inferences	▪ Request to produce explanations based on students' previous explanations (and identified by the teacher as close to the scientific accepted ones). ▪ Teacher's elaboration of generative questions. ▪ Request to compare systems that behave differently from each other when students were already able to explain the behaviour of one of them.	Production of mental model. Expression of the model. Tests of the model.	2 3 4
Generalisation	▪ Presentation of a new context in which students could try to extend their possible inferences from the process they had experienced, thus providing evidence of the knowledge they had built during the modelling activities.	Assessment of the resulted model.	4

Figure 2. Summary of the relationships between the analogical reasoning sub-processes experienced by students in different modelling stages and activities.

Our results showed that specific requests from of the modelling activities (mainly those related to the production, expression, and tests of students' models), as well as some teacher's actions when conducting the process (mainly the promotion of discussions between students, the elaboration of generative questions, the request for explanations concerning the codes of representations used in different models, and the request for justification of all their expressed ideas) have clearly favoured the occurrence of all the analogical reasoning sub-processes (including those that are not common in students' analogical reasoning).

Besides these relationships, we can also discuss other contributions from the drawing of analogies in the modelling-based teaching context. One of them concerns the visualization of sub-microscopic entities (and relationships between them) from the observation of macroscopic phenomena (Justi & Gilbert, 2006). As those students had already studied the chemistry topic, we suppose their previous learning about it was insufficient for supporting students' production of initial representations (concrete models and analogies) at the sub-microscopic level that included information concerning the interaction between particles and the intensity of such interactions. In the teaching situation analysed in this study, when the teacher provide them opportunities to express their own comparisons, she could realise that, although they were asked to make representations at the sub-microscopic level, they established mere appearances matches (those characterised by the mapping of macroscopic properties between the compared domains). This has supported the teacher's decision of discussing the meaning of such levels, and making clearer to students what they should represent and explain in their models. Moreover, the simultaneous expression of students ideas through concrete models and analogies, and the teacher's request for explanations concerning the codes of representation used in each model have also favoured the teacher's access to some students' ideas, as well as her following actions aiming at favouring students' reasoning at the sub-microscopic level.

Our results also support our view that the use of modelling-based activities like those used in this study can facilitate the evolution from the establishment of mere appearance matches to the drawing of analogies. This is so because relational comparisons are made when a more advanced knowledge about a given domain is being developed, or has just been developed (Vosniadou, 1989), that is, when students are already able to integrate the macro and the sub-micro levels in building a more comprehensive understanding (Justi & Gilbert, 2006).

In this study, we had evidence that the modelling-based activities provided opportunities for that students experienced all the analogical reasoning sub-processes in a way similar to the one scientists experience when building scientific knowledge. Following the process of evolution of students' ideas in the direction of those accepted in science, we had evidence that the drawing, expression, and changing of students' analogies contributed to their learning about the chemical topic. On the other hand, other studies would be necessary in order to investigate if the drawing, expression, and changing of students' analogies can also support students' learning about the process of building scientific knowledge – which is also one of the aims of modelling-based activities produced from the Justi and Gibert's modelling diagram perspective.

Finally, as our study has shown, the involvement of students in all the analogical reasoning sub-process cannot be viewed as an autonomous process, that is, the teacher should guide the students in performing specific sub-processes. Therefore, it is essential to include discussions about modelling-based teaching, analogical reasoning, and teachers' actions that may foster the integration of such processes in teachers' educational contexts. This may result in the development of specific elements of their pedagogical content knowledge, which may support them in facing the challenges of conducting more authentic and effective science education.

ACKNOWLEDGMENTS

We would like to thank the Brazilian agencies CNPq, CAPES, and FAPEMIG for the financial help for conducting this study and attending the ESERA Conference.

PROSPECTIVE SCIENCE TEACHERS' APPRECIATION OF SCIENCE: THE CASE OF THEORY OF EVOLUTION VS. INTELLIGENT DESIGN

Ebru Z. Mugaloglu[1] *and Sibel Erduran*[2]
[1] Bogazici University
[2] University of Bristol

Abstract: The study aimed to explore the prospective science teachers' appreciation of science in the case of evolution vs. intelligent design (ID). It introduced a proxy indicator of "appreciating science" in the case of evolution theory. "Appreciation of science" was defined as recognising the value or excellence of science and therefore choosing the scientific explanation between the clashing worldviews in question. Data were collected from 31 prospective science teachers' written arguments in the context of evolution versus intelligent design (ID). Four distinct groups of claims were identified following qualitative analyses of the written arguments: (a)"Accept Evolution and Teach Evolution only", (b)"Accept Evolution & ID and Teach Both", (c)"Accept Evolution, Teach Evolution and Talk about ID" and (d)"Do not Accept Evolution and Teach ID only". We concluded that %39 of the participants did not appreciate the theory of evolution in explaining the origin of species. We also concluded that accepting a scientific theory was a necessary but not a sufficient condition for appreciating science because 32% of the prospective science teachers accepted evolution and ID as science and equated ID with evolution theory. Furthermore prospective science teachers who appreciated science and who did not appreciate science on the basis of our definition of appreciation, refer to the same aspects of nature of science (NOS) such as tentativeness and testability to justify their positions about teaching evolution and/or ID. This outcome implies that either these prospective science teachers do not have a clear understanding contemporary NOS views or these aspects of NOS are not sufficient in enhancing prospective science teachers' understanding of evolution. In the context of the broader goals of scientific literacy, one of the implications of the study is to develop and integrate activities in teacher training programs in order to enable prospective science teachers to understand the nature of scientific theories and to distinguish a theory from a pseudo scientific explanation. We suggest that improved understanding of NOS will facilitate better appreciation of science.

Keywords: appreciation of science, evolution, intelligent design

INTRODUCTION

In a scientifically literate society, people are expected to distinguish between what is science and what is not, and construe a scientific theory as the best explanation for a particular natural phenomenon at a particular time period. For instance, evolution theory is a scientific theory explaining the origin of species whereas intelligent design (ID) is a pseudo-scientific explanation about the origin of life. The ability to distinguish a scientific explanation from a pseudo-scientific explanation is an important aspect of scientific literacy. However, according to a survey in 2006, in countries such as Turkey and US, public acceptance of evolution theory is very low (Miller, Scott, & Okamoto, 2006). Peker, Comert & Kence (2010) indicated that the acceptance of evolution as a scientific theory in Turkey was low not only in public but also among undergraduate students in science education, biology education and biology. Peker et al's study (2010) illustrated that only 27.75 % of undergraduate students with a science background, who were supposed to teach evolution in Turkey, accepted evolution as a scientific theory. It is also worthwhile to note that there are wider institutional and cultural concerns that impact how evolutionary theory is perceived and communicated in Turkey. For example, in 2009, a special issue of the official magazine of the Turkish Scientific and Technical Research Council (TUBITAK) about Charles Darwin and the theory of evolution were censored just before it went to press (Nature, 2009). In addition to this censorship, ID is being disseminated in Turkey quite systematically and the social pressure increases on teachers to teach it as science. "Turkey is now a major source of the creationist propaganda outside the USA, and is especially significant in relation to its influence on Muslim populations in Europe" (Cornish-Bowden & Cardenas, 2007, p.113). These efforts are sometimes supported politically in the European Union (EU) and elsewhere. For example, in a response to an EU Resolution, European Centre for Law and Justice (2007) described ID as a scientific theory and equated it to the theory of evolution.

FRAMEWORK AND PURPOSE

Wider theoretical context for the study of scientific vs. pseudo-scientific explanations is epistemology. Within traditional epistemology, it is widely accepted that belief, truth and justification are the necessary conditions of knowledge. This is known as the justified true belief (JTB for short) theory (Musgrave, 1993). So, if knowledge is considered as one of the primary outcomes of science education, then it follows that science teachers are also responsible for facilitating their students' acquisition of scientific beliefs. However, teaching science does not guarantee a change in students' potential inconsistent beliefs especially about science topics such as evolution or astronomy. Smith and Siegel (2004) argue that science education must aim for understanding rather than knowing so that beliefs of students do not become an issue in science classes. In other words, unlike knowing, believing is not a necessary condition for understanding. Instead of believing, Smith and Siegel (2004) emphasize appreciation of justifications as one criterion of understanding. Moreover, in order to develop public understanding of science, it is "necessary for students to develop an appreciation of both the power and limitations of scientific knowledge claims" (Driver, Leach, Millar and Scott, 1996).

In the Oxford English Dictionary (2010), to 'appreciate' is defined as "to recognize as valuable or excellent". The present study introduces a proxy indicator of "appreciation of science" in the case of evolution theory. The topic of evolution is quite significant in science education as evidenced, for instance, by the dedication of a special issue of *Science & Education* Journal in 2010, and therefore perfectly fits the purpose of introducing a proxy indicator of appreciating science. Broadly speaking "appreciation of science" is defined as recognising the value or excellence of science. Moreover, Deboer (2000) suggests enhancing public understanding and appreciation of science for the larger goal of scientific literacy. For the purpose of this study we expect appreciation of science to be inclusive of favouring scientific explanations, for example, choosing the scientific explanation when presented with clashing worldviews about a critical issue. In order to promote appreciation of science in science classrooms, then, teachers would be expected to place a higher status to the theory of evolution as a scientific theory than to intelligent design. Within this framework, the present study aimed to explore the prospective science teachers' appreciation of science in the context of evolution vs. intelligent design (ID). In order to approach the research problem, prospective teachers' written arguments were investigated to outline how they chose to justify their preferences to teach evolution and/or ID in a science class. We define argument as justified claims about a position taken, in this context, claims about evolution vs. ID –a definition which is consistent with others in the literature (Erduran, 2007). Moreover, we analysed how prospective science teachers referred to widely taught aspects of Nature of Science (NOS) in order to justify their positions. Thus, it was aimed to analyse the role of their NOS views in their preferences about teaching evolution and/or ID. According to mainstream NOS views, scientific knowledge is: (a) Tentative, (b) Subjective Based on empirical evidence, (c) Theory-laden, (d) the product of human imagination and creativity,(e) inferential, (f) influenced by society and culture as well as by scientists' values and experiences (Abd-el-Khalick, 2001; Schwartz & Lederman, 2002).

METHOD

The study was guided by the following research questions: (a) What is the nature of prospective science teachers' appreciation of evolutionary theory in Turkey? (b) What is the role of teachers' views on the nature of science (NOS) in relation to their position regarding the theory of evolution?

Data were collected from prospective science teachers in a state university in Turkey. The university accepts students from all over Turkey who are successful in the nationwide University Entrance Examination. This examination is centrally organized by the Student Selection and Placement Centre every year, and all high school graduates who want to be science teachers must sit for it. Successful students may attend a four-year program in a Faculty of Education. Upon graduation, the prospective teachers in this study would be qualified to teach science in primary schools (grades 6–8). The sample comprised 31 third- and fourth-year students: 11 male and 20 female.

The participants watched the NOVA documentary film titled "Judgement day: Intelligent Design on Trial" (2007). The film problematises the teaching of evolutionary theory versus intelligent design, and is based on a true story of conflict in a community and a school district in the United States. After watching the NOVA documentary film, prospective teachers were asked to write a position paper to clarify and justify their individual positions on teaching evolution and designed in a science class. The written arguments of the prospective teachers were analysed to identify their appreciation of science. Moreover, two prospective science teachers (one who appreciated evolution and one who did not appreciate evolution) were chosen for case study analysis. In both cases, statements of prospective science teachers were scrutinised so as to reveal how their NOS views influenced their positions. More specifically, we traced how prospective science teachers referred to characteristics of science and scientific knowledge such as tentativeness, subjectivity, falsifiability, theory-ladenness, explanation of nature, natural or supernatural causality, method and inquiry processes including questioning, hypothesis, observation and data collection.

RESULTS

As a result of qualitative analysis of written responses (Table 1), four distinct groups of arguments were identified:

Group (a)-Accept Evolution and Teach Evolution only: The first group included 15 prospective science teachers. They clearly accepted evolution as a scientific theory. As for their positions on their future science classes, all prospective science teachers in this group argued in favour of only teaching evolution in science classes. Analysis of their arguments showed that they gave a higher status to the theory of evolution as a scientific theory than to ID.

Group (b)-Accept Evolution & ID and Teach Both: The second group included 10 prospective science teachers. They considered ID as a scientific theory and equated it with the theory of evolution. As for teaching evolution and/or ID in their classes they opted for teaching both.

Group (c)-Accept Evolution, Teach Evolution and Talk about ID: This group included 4 prospective science teachers. Similar to the prospective teachers in Group (a) they accepted evolution as a scientific theory and argued in favour of teaching evolution in science classes. However, differently from Group (a), they also argued that ID should be mentioned in science classes as a pseudo scientific explanation. Yet, they gave a higher status to the theory of evolution as a scientific theory than to ID.

Group (d)-Do not Accept Evolution and Teach ID only: The fourth group included 2 prospective teachers. They clearly rejected the theory of evolution based on their religious beliefs. They argued that evolution theory imposed atheism and in this sense it was also religious. They also argued that science was not able to answer the origins of life as the question was not scientific. They argued that the best role for science in this issue was to work on how the Designer created the universe. Based on these justifications they opted for not only teaching ID in science classes but also teaching against Darwinism and evolution.

Table 1. The results of the appreciation of science analysis

	Appreciate evolution		***Do not appreciate evolution***	
	Accept evolution & Teach evolution	*Accept evolution & Teach evolution and mention ID*	*Accept evolution & Teach both evolution and ID*	*Do not accept evolution & Teach ID and mention evolution*
Total (n)	15	4	10	2
Total (%)	48.4%	12.9 %	32.26%	6.5 %
Total (%)	61.3 %		38.70 %	

Case Study Analysis

Two cases of prospective science teachers were selected for a detailed analysis of the role of nature of science (NOS) views in justifying their positions in teaching evolution and/or intelligent design in a science classroom.

The first case is from group (a), therefore, classified as “appreciates evolution”. The prospective science teacher argued that evolution was a scientific theory whereas ID was not science. Therefore, he preferred teaching evolution theory. While justifying this position, he referred to certain aspects of NOS. These included definition of ‘theory’, tentative, testable, and falsifiable nature of science. Regarding NOS he stated:

> *Yes, t**heory** is not a fact but it is the best explanation we have about the rules of nature. ...all scientific explanations are **tentative and testable** ...scientific knowledge should be **testable, falsifiable** and **tentative.***

While arguing against ID he stated:

> *The followers of intelligent designers do not have much scientific data or explanations... ID is not a scientific explanation or a theory because all scientific explanations are **tentative and testable**...The proofs of ID were not scientific because scientific knowledge should **be testable, falsifiable and tentative**.*

The second case is from group (b), therefore classified as "does not appreciate evolution". This prospective science teacher argued that both evolution and ID are scientific in nature. Therefore, he opted for teaching ID as an alternative theory to evolution. Regarding NOS, ID and evolution he respectively stated the followings:

> *Scientists are not totally **objective.** They defend their own **theories.** But science is **objective**. In order to be **objectiv**e students should learn different points of view.*

> *ID proponents say that "nature of an intelligent cause or agent may not be directly **observable**, its effects on nature can be detected. When we think about these, it can be considered as science. İt[ID] is just a **theory** and it is one of the explanations of origins of species. You are free to believe whatever you want…Evolution theory can be considered as science because some concepts of the theory are **observable** by the methods of science.*

> *Some scientists accept this theory [evolution] as valid because of existence of many **evidences** that support the theory. Despite there are **evidences** about the theory, every new findings has potential to refute this theory **[tentativeness**]*

So, according to this case, in order to be objective, students should learn both points of view. In this sense, they possess an equivalent position in the science classroom. While justifying this position, he referred to certain aspects of NOS such as objectivity, observable, evidence, and tentativeness, some of which were the same aspects as in Case 1.

CONCLUSIONS AND IMPLICATIONS

If prospective science teachers appreciate science and a group of prospective science teachers is examined in terms of their positions about teaching evolution and ID as science, then it is expected that they would favour evolution compared to ID in a science class. However in the present study, 38.7% prospective science teachers preferred teaching both or only intelligent design as a scientific theory. Therefore, the group of prospective science teachers did not appreciate science in the sense that we are considering "appreciation of science". Hence, based on the results of the study**,** we conclude that the prospective teachers in the groups (a) and (c) appreciate science (as specified in our conceptualisation "appreciation of science") whereas the participants in the group (b) and (d) do not appreciate science. Considering that all participants are prospective science teachers, the ratio who do not appreciate evolution theory can be considered to be quite high and thus of concern.

We also concluded that accepting a scientific theory was a necessary but not a sufficient condition for appreciating science. In other words, % 32 of the prospective science teachers accepted evolution in group (b). However, group (b) also accepted ID as science and equated ID with evolution theory. So, acceptance of evolution by itself might be a misleading criterion for science educators. Instead, appreciation might be a better criterion for evaluating the case of evolution/ID. Moreover, from the case analysis, it was seen that prospective science teachers who appreciate science and who do not appreciate science refer to the same aspects NOS such as tentativeness and testability to justify their positions about teaching evolution and/or ID. This implies that either these prospective science teachers do not have a clear understanding contemporary NOS views or these aspects of NOS are not sufficient to enhance prospective science teachers' appreciation of evolution. Therefore there is a need for further studies about the role of prospective science teachers' NOS views in their appreciation of science.

As for the goal of scientific literacy, the implications of the present study are at least two-fold. First, activities, which enable prospective science teachers (a) to understand broader aspects of a scientific theory and (b) to distinguish a theory from a pseudo scientific explanation should be developed and included in teacher training programs. Second, as accepting a scientific theory is not a sufficient condition for scientific literacy, teacher training programs should emphasize appreciation of science to ensure that future teachers recognise the value and excellence of science.

OPENING UP VALUES THROUGH HISTORY AND PHILOSOPHY OF SCIENCE

John Oversby[1]
[1]Institute of Education, Reading University, Reading, RG6 1HY, UK Email: j.p.oversby@reading.ac.uk

Abstract: The 30 month, 8 country, EU History and Philosophy in Science Teaching (HIPST) project was established in February 2008. the UK part of the project has focused on three themes: a) the role of measuring in characterising the concept of temperature in history; b) induction as a historical method for establishing concepts of acidity; c) the historical use of the paper tools of chemical formulae and chemical equations to promote thinking about chemical processes. The first two themes are suitable, and are being trialled in lower secondary schools, with 5 comprehensive classes of Year 7 (11/12 year old pupils), in the South of England. the third theme is suitable for upper secondary pupils.

The materials produced for the first theme have been trialled and reviewed. The results so far have established the strength of a collaborative two cycle approach, involving a researcher from Higher Education, and practicing teachers in schools, producing relevant and robust resources for subject knowledge and the Nature of Science. Co-teaching has proved to be a successful tool for improving and increasing teacher subject knowledge about science and the history of science. Equally valuable, co-teaching has been a successful method for introducing pedagogical innovation, in comparison with a wiki, which has been less well used.

Pedagogical innovations that have engaged most pupils have included producing play scripts of scientific stories, and newspapers written in simple language. Using pupil work as a source of material for newspapers has also been an important innovation. the pupil newspapers have also served as a source of information for the teachers. Some new activities have been developed: lack of equipment in schools and skills of technicians was a barrier, and has led to specific training for the latter.

INTRODUCTION

The science education community's values are embedded, often implicitly, in its intended curricula. For example, the Science National Curriculum in England for 11 – 14 year olds (QCDA, 2009) states that: 'Pupils learn how knowledge and understanding in science are rooted in evidence. They discover how scientific ideas contribute to technological change – affecting industry, business and medicine and improving quality of life. They trace the development of science worldwide and recognise its cultural significance.'
Under Cultural Understanding, the same National Curriculum requires pupils to ‘recognise that modern science has its roots in many different societies and cultures,

and draws on a variety of valid approaches to scientific practice'.
The American Association for Advancement of Science (Project 2061) (AAAS, 1993, 2009) has 'The images that many people have of science and how it works are often distorted. The myths and stereotypes that young people have about science are not dispelled when science teaching focuses narrowly on the laws, concepts, and theories of science. Hence, the study of science as a way of knowing needs to be made explicit in the curriculum,' with development of some of the history to exemplify what should be done. Within the domain of History of Science, we seem to have variable and often rather weak guidance on its inclusion in Science Curricula.
Williams (2002) surveyed the history of science in textbooks in England in 1999, following the integration of science into the mainstream school science curriculum. He notes that, in the related history curriculum, pupils have to have: chronological understanding; knowledge and understanding of events, people and changes in the past; historical interpretation; historical enquiry; and organization and communication. He used this framework to assess the place of history of science in readily available textbooks. His conclusions included (page 90):

- 14 – 16 physics has a larger volume of unexplained names in the history of science than biology and chemistry;
- the history of science is often included as a non-essential 'add-on' and serves little purpose in developing ides and/or concepts;
- few accounts of the lives of scientists are given or how they worked;

Höttecke (2009) in his ESERA paper acknowledged the importance of History and Philosophy of Science towards school teaching, and the dearth of research about and curriculum resources for HPS teaching in schools. Höttecke gave the following research analysis of the impact of teaching HPS in Physics.

RESEARCH QUESTIONS

1. What are the purposes of including History and Philosophy of Science (HPS) in school curricula? What HPS is embedded in curricula?
2. What is presently known about the effect of HPS teaching in schools?
3. How do teachers respond to an explicit HPS teaching programme?
4. How do young learners respond to an explicit HPS teaching programme?

METHODOLOGY

1. The author undertook a desk study of National Curricula for Science, and of textbook resources. This was supplemented by a national meeting of researchers. teacher trainers, a philosopher of science, textbook writers, members of learned scientific societies, and a museum presenter.
2. The author undertook a desk study of literature relating to the effect of HPS teaching in schools
3. Three teachers undertook to teach a module on temperature to explore the effect of measuring on validating, and developing the reliability and accuracy of scientific equipment. The teachers took part in discussions by email, face to face conversations

that were recorded by hand, and one by constructing a reflection log
4. Teachers in two schools volunteered to trial materials with a total of 150 pupils aged 11-12 years old. Data collection included open-ended written questions, recording of learning in notebooks, field observations by the author, debriefing discussions by the author that include reports agreed with the teachers, pupil play scripts about a historical event, and a pre- and post-test about pupil views on HPS.

DETAILS OF THE PROGRAMME

The project that includes this work is part of the EU funded (FP7) History and Philosophy in Science Teaching (HIPST) project (HIPST, 2008-2010). The project is led from Germany and has activities in 8 European countries devoted to producing trialled resources for teaching HPS in schools, museums and universities. The project also aims to develop teachers' personal subject matter knowledge, pedagogical skills, especially in using innovative methods, and to introduce explicit historical and philosophical thinking into science teaching. In the case of philosophical considerations, this is directly linked to the Nature of Science, and in particular in the UK to the How Science Works part of the prescribed curriculum.

The UK part of the programme has three active themes:
a) historical characterisation of concepts through measuring, in the context of temperature;
b) historical conceptual identification and change, in the context of acidity;
c) historical development and use of paper tools, in the context of chemical formulae and chemical equations.
Themes a and b are being conducted with pupils in lower secondary schools, Theme c will be conducted in both lower and upper secondary schools. This paper focuses mainly on theme a, and is partly work in progress.

The topic of measuring is part of basic scientific training in UK lower secondary schools. Pupils have studied particle ideas as concepts, and it is important that the curriculum topic meshes with the stated curriculum.

Philosophical issues
a) What are the purposes of measuring in the scientific community?
b) What is meant by validity, reliability and accuracy in scientific measurement?
c)

Historical issues
a) Is the human body a valid, reliable and accurate thermometer?
b) What is meant by standardisation, and how was it carried out for liquid-in-glass thermometers?
c) How was the constant-volume gas thermometer developed and used?

Teacher materials
A web site (www.ukhipstinstruments, wikispaces.com) has been constructed for teachers engaged in the project. The web site has these major components:

a) a teachers' subject knowledge section incorporating scholarly material on subject matter knowledge about temperature, research on typical misconceptions, pedagogical content knowledge, and philosophical information,
b) a context section incorporating historical chronological information about scientific discoveries, significant cultural events and significant political events,
c) a scheme of work to show lesson progression with conceptual, misconceptions, historical elaboration, and philosophical elaboration,
d) a teachers' section that elaborates each lesson in turn.
In addition, the project has produced simple newspapers. There are staff newspapers to share nes about the project as it progresses in schools. There are pupil newspapers, with relevant historical information about how temperature was measured in history, puzzles for pupils, reports of pupil surveys with friends and parents about what temperature is and how scientists measure, and a selection of play scripts about Gmelin's expedition across Siberia at the behest of Catherine the Great. The play plots Gmelin's report of the lowest temperature of -84.4C and the subsequent comment 50 years later by Thomson that the mercury would have frozen before then. The play scripts are used as a measure of pupil understanding of a problem in measuring temperature.

EVIDENCE

This report is based on the work of three teachers in two UK comprehensive schools, working with a total of five classes of 11-12 year old pupils, grade 7. Approximately 140 pupils have been involved so far. The study is still in progress. Up to date data and interpretation will be available for the conference.
1.
The Science National Curriculum in England for 11 – 14 year olds (QCDA, 2009) states that:
'Pupils learn how knowledge and understanding in science are rooted in evidence. They discover how scientific ideas contribute to technological change – affecting industry, business and medicine and improving quality of life. They trace the development of science worldwide and recognise its cultural significance.' It also states that pupils should be 'using scientific ideas and models to explain phenomena and developing them creatively to generate and test , and be critically analysing and evaluating evidence from observations and experiments'.
Under Cultural Understanding, the same National Curriculum in England requires pupils to 'recognise that modern science has its roots in many different societies and cultures, and draws on a variety of valid approaches to scientific practice'.
Internationally, there are variations in the emphasis paid to these issues. In recent Australian proposals, science is simply described as a 'human endeavour' with little reference to any historical outworking of this process. The New Jersey elaboration of the US Framework for Science states one aim of science is 'to show students that scientific ideas and theories have a history of their own by tracing the evolution of our most important present-day paradigms' (New Jersey, no date) The American Association for Advancement of Science (Project 2061) (AAAS, 1993, 2009) has 'The images that many people have of science and how it works are often distorted. The myths and stereotypes that young people have about science are not dispelled when science teaching focuses narrowly on the laws, concepts, and theories of science. Hence, the

study of science as a way of knowing needs to be made explicit in the curriculum,' with development of some of the history to exemplify what should be done. Urevbu and Omoi (2005) describe in detail one approach to using the history of science in Nigeria in their paper delivered to the IHPST 2005 Leeds conference but do not provide evidence of success.
Williams (2002) examined UK science textbooks for history of science content. The minimal content was an add-on, with little of the context in which the scientists worked, or about them as human beings. The history content is hardly used to develop conceptual understanding. Regrettably, there also significant numbers of errors in many textbooks.

2. Relatively little research is known about the effect of teaching HPS in schools and that which has been so far explored has mainly been in the physics domain (e.g. Höttecke, 2009 and Galili, 2009). Many researchers assert potential benefits, such as exploring difficult concepts through historical data, but there is only very modest evidence of success in this area in the literature (but see Wandersee, 1986, for one such example).

3. The teachers taking part in the trials programme are volunteers, so generalisation to other cases can not easily be made. However, these are the most positive conditions, so lack of success in these cases would be a serious setback. The main teacher in one school is a senior science teacher, and in the second school the main teacher is strongly supported by the leader of the science department. The teachers readily accept their initial lack of knowledge about the history of science, hence the production of pupil newspapers for the teachers' knowledge as much as for the pupils. They also accept their initial lack of knowledge about the philosophy of measuring, which has been developed through discussion with the author. A paper on measurement has been incorporated into the temperature wiki. The teachers claim, with strong justification, that lack of time in the face of persistent and demanding requirements for bureaucratic reporting make it difficult for them to devote significant time to studying for the project. Co-teaching, by the researcher and the teacher of each class, has been the major input source for their learning of historical and philosophical knowledge and of innovative pedagogical methods. Other sources of information, such as the web site, have played a very minor role so far, from debriefing interviews with the teachers.

4. There has been a wide variation in the way that pupils have engaged with the course. The increased emphasis on an adequate literacy base for pupils involved in the project has meant some difficulties, especially for some boys who seem to be the ones with the most serious problems in this regard. This has led, in some classes, to distracting behaviour by these pupils. The project has adopted a pragmatic approach to partially addressing the literacy issue by simplifying the language used, for example in the project pupil newspapers. However, the project participants have agreed that there is a limit to the extent that this can be done without compromising the accuracy of the ideas involved. This has meant that a small proportion (perhaps three or four in each class) have been somewhat disenfranchised from accessing some resources, such as the newspapers. Nevertheless, the great majority of the pupils show a positive attitude, in asking questions, in engaging with the practical work, in carrying out extra work at home, and in putting in extra personal time to completing play scripts. That these are often girls is only to be expected from the results of the

ROSE survey (ROSE, nd), that indicates girls dominating interest in humanistic science, and in more creative methods of recording their findings. Pupil recording of their findings in the form of annotated drawings suggest that the majority are understanding the science, the history and the philosophy in the lessons. The issue of literacy is a factor with a few pupils in the project recording their data, so that this evidence can not be collected from all.

CONCLUSIONS

The project has been successful in these respects:

1. Appropriate resources have been produced for teachers and pupils.
2. A rich dedicated web site has been provided, providing suitable guidance for both teachers and pupils.
3. The project is rather unusual (Innovative) in that the teachers are highly influential in the progress of the trials and resource production. This collaborative action between a colleague in Higher Education and teachers in schools is rather unusual.
4. The resources provided are innovative in a number of ways:

a) the use of web sites with optional information and opportunity for blogs, discussion and teachers to create their own pages and upload their own files is innovative;
b) the use of newspapers for revealing history of science, in pupil-level language, is unusual;
c) the use of newspapers in which teachers and pupils can make their own contributions, is innovative;
d) recreating historical experiments is unusual
e) the use of play scripts for recording and assessing learning is unusual
f) the use of newspapers for dissemination of progress to project members, including teachers, is unusual.

IMPLICATIONS FOR TEACHING

The project represents work in progress. Nevertheless, there are some clear implication from the project to date:

1. More resources for teaching HPS are needed and have been provided by the project.
2. Co-teaching is a powerful method for developing teachers' subject matter knowledge and innovative pedagogical skills.
3. Curriculum materials that mesh with the curriculum are more likely to be readily accepted.
4. Teachers need more time if curriculum change is to be securely embedded.
5. Individual pupil difficulties with literacy is a major barrier to engagement with science.
6. Some innovative pedagogies such as producing play scripts, and newspapers, can support increased engagement by pupils.
7. The project has unearthed some insecure learning in particle ideas that limit application e.g. use of the gas thermometer. The project has demonstrated a requirement for some changes to teaching the existing curriculum.

Abstract: In the Latin-American Project of Evaluation of Attitudes Related to Science, Technology and Society (acronym in Spanish: PIEARCTS), teachers and students from different countries were asked about their opinions on gender differences regarding Science. More than thirteen thousand students and teachers participated in the project. In this work, we analyze the results obtained by means of the Questionnaire of Opinions on Science, Technology and Society regarding the Internal Sociology of Science, focusing on two items, which inquire about the characteristics of scientists: Gender Equity (GE) and Women´s underrepresentation (WU) in Science. The results show that, in the overall sample from the different countries, the question on GE appears among those which present more positive attitudes in almost all the countries. On the other hand, as regards WU, Spain and Colombia present the most positive attitudes, whereas Brazil is among those with the most negative views. Nevertheless, the sentences corresponding to these topics appear both among the more positive and among the most negative. Women seem to be more conscious than men of the fact that the relationship between women and Science continues to be problematic. In the majority of the variables where they have found significant differences between women and men, it is the women who show a more suitable attitude.

Keywords: gender equity, nature of Science, Science – technology – society, evaluation of conceptions, teachers' thinking.

BACKGROUND, FRAMEWORK, AND PURPOSE

The traditional view of Science is shown as neutral, rational and objective, and, even if this conception has been modified thanks to the critical trends of Philosophy of Science, which considers Science a human activity (Toulmin, 1972; Fourez, 1992; Feyerabend, 1978) and, therefore, intrinsically subjective and dependent on the values of the people who construct it and on the theories on which it is based. The image or model of Science expressed by the majority of the people does not concur to these critical trends. One of the conceptions that stand out is a stereotyped model which conceives Science as the search for the objective truth about the physical world with an androcentral, positive and mystified view of this discipline that portrays man as the conqueror and controller of nature (Solsona, 2002, p.49). Teachers´ view of Science is very important since it is transmitted to students and; thus, it is disseminated and perpetuated. This transmission of the views towards Science regarding gender is often produced without the teachers' conscious awareness, since it is also supported of by the use of sexist language on textbooks and other curricular material.

During the last few years, studies about the situation of female scientists in Spain done by the Spanish Foundation for Science and Technology (Spanish acronym: FECYT) (2005), as well as in Latin America (Pérez Sedeño & Gómez, 2008), indicate that women are under represented in great part of the scientific disciplines. Opinions about this situation show that these realities are usually considered natural and inevitable. To modify this situation in the Scientific sphere, a change in the sphere of Education must be produced. One of the most important demands that are done to the educational system is related to the real capacity which the system has of being a tool that guarantees equality of opportunities (Freire, 1996). According to Subirats (2006, p. 229) “the path that is taking us from a situation of marginality and subordination to a situation of autonomy and intervention in mass decision-making processes is started through the educational system …”

RATIONALE

In this work we will present and analyze teachers´ and students´ opinions about gender equity and women under-representation in Science. These opinions were drawn from the corpus of the Latin American Project of Attitude Assessment about Science and Technology (Spanish acronym: PIEARCTS). The teachers who participated in this project work at the primary, secondary or higher educational level and come from all kinds of backgrounds. The students participants from different countries and are either finishing high school or attending university. Our objective is to show a diagnosis that allows us to answer, among others, the question posed by Ana Sánchez Bello (2002): What is the educational system’s failure since situations of social inequality regarding gender still continue to happen?

METHODS

Sample and instrument

This paper draws data from the international cooperative research project PIEARCTS, which intends to identify the nature of Science and Technology (NoS&T) beliefs across seven Iberian-American Spanish and Portuguese-speaking countries. NoS&T conceptions are assessed through the Questionnaire of Opinions on Science, Technology and Society (Spanish acronym: COCTS) (Manassero, Vázquez y Acevedo, 2003). This research tool allows easy and reliable applications to large representative samples. The PIEARCTS research team consensually selected 30 items that accomplish a balanced coverage of Science, Technology and Society issues. These items were distributed into two 15-item paper and pencil research booklets (F1 and F2). The participants in the study were 13,146 students and teachers (practitioner and pre-service) that anonymously completed a booklet, whose responses are scaled into a set of attitudinal indexes. Each participant responded one of the two questionnaires; approximately half of the participants answered Form 1 (7094), and the rest completed Form 2 (6052). In this work the results obtained in two items regarding the Internal Sociology of Science are analyzed, the first item refers to Gender equity (GE) and the second to Women´s underrepresentation (WU) in Science. As regards GE, participants are asked to reflect their opinion on the following:

- *Working in Science or technology, women would make a good scientific work in much the same way that a good scientific man:*

There are no differences between men scientists and women scientists in terms of the way they do Science:

A. because all good scientists do the work in the same way
B. because men scientists and women scientists have the same pre-service
C. because, above all, men and women are equally intelligent
D. because men and women are equal in terms of what it takes to be a good scientist
E. because we are all equal, regardless of the work we do
F. because any difference in the way that scientists work in Science are due to individual differences. Such differences have nothing to do with being male or female

G. Women in Science would work somewhat differently, because by nature or education women have different values, opinions, perspectives or characteristics (such as patience)
H. Men would work in Science a little differently, because men perform this type of work better than women
I. Women in Science would probably work better than men, because women must work harder in order to compete in a male-dominated field, such as Science.

In terms of women's under-representation (WU) in Science, the participants were presented with the following scenario:

- *Today in our country, there are much more men than women scientists. The MAIN reason for this is*:

men are strongest, fastest, brightest and better to concentrate on their studies

A. men seem to have more scientific capacity than women, women may excel in other fields
B. men are more interested in Science than women
C. the traditional stereotype that exists in society is that men are smarter and more dominant while women are weaker and less logical. This belief has resulted in more men becoming scientists, although women are as capable as men in Science
D. schools have not done enough to encourage women to choose Science courses. Women are as capable as men in Science
E. until recently it was thought that Science was a vocation in men and it was expected that most women work at home or in jobs traditionally performed by women, so the public image of Science has discouraged women -while encouraging men- to become scientists. But this is changing today: Science is becoming a vocation in women and more and more females are expected to work in Science
F. women have been discouraged or not allowed to enter the scientific field. Women are just as interested in Science and just as capable of doing so as men are. However, established scientists (who are men) tend to discourage or intimidate potential women scientists
G. There is NO reason to have more men scientists than women scientists. Both are equally capable of being good at Science and the opportunities today are similar

Procedures

The respondents rate their agreement on a scale from 1 to 9, in which 1 is used to show total disagreement and 9 to show total agreement, on each sentence item. These items are scaled into quantitative homogeneous attitudinal-belief indexes (-1, +1), whose meaning represent the grade of correctness, according to the current knowledge from History, Philosophy and Sociology of S&T (Vázquez & Manassero, 1999; Vázquez, Manassero & Acevedo, 2006). Besides, the participant's understanding of NoS&T is further represented by three indexes for the three categories in each item and the whole item index. This plan describes the participant's thinking by means of over one hundred and fifty invariant indexes (sentence, category and item indexes).

The index scores allow the use of inferential statistics for hypothesis testing, which can be applied to compare groups (last-year high school vs. last year-university students, pre-service vs. in-service teachers), or to set up cutting points for identifying the strengths (highest positive), weaknesses (lowest negative), and neutral beliefs (Vázquez, Manassero & Acevedo, 2006). The criteria to achieve relevance are the statistical significance ($p < .001$), and the effect size of the differences (differences measured in standard deviation units; $d > .30$).

RESULTS

In the overall sample of different countries, there are more positive GE attitudes in almost every country (except Mexico) and more positive WU attitudes in Spain and Colombia. On the other hand, these attitudes are more negative in Brazil. Nevertheless, sentences regarding these items appear both among the most positive and the most negative attitudes.

The attitudinal indexes of sentences that have the highest scores and positive above the cut point (half of standard deviation) are:

- To GE item, sentences D and F (Argentina, Colombia, Mexico, Spain and Portugal), and H (Argentina, Colombia, Spain and Portugal).
- To WU item, sentences A (all the countries), B (Argentina, Brasil, Colombia and Spain), C (Brasil, Spain, Mexico and Portugal), E (Brasil), F (Brasil and Colombia) and G (Brasil).

The attitudinal indexes of sentences that have the lowest scores and negative below the cut point (half of standard deviation) are:

- To GE item, sentences A (Argentina, Colombia, Spain and Portugal), C, B and E (Argentina, Colombia and Spain) and I (Colombia).
- To WU item, sentences H (Argentina, Spain, Portugal and Brasil).

Differences between groups of teachers

In Table 1 we show the results obtained for each of the countries, in terms of the index average for the whole item and to the standard deviation units of both items, for the groups of Exact and Natural Sciences (Science) and Human and Social Sciences (Non-Science), with the statistical significance corresponding to the differences between both groups.

Table 1. Results of Science and Non-Science Groups of all the countries

Country	Science		Non-Science		Signific.
	Average index	Standard deviation	Average index	Standard deviation	
Gender Equity Item					
Argentina	0.203	0.227	0.190	0.235	0.620
Brazil	0.090	0.305	0.132	0.317	0.198
Colombia (B.)[1]	0.103	0.277	0.145	0.293	0.177
Colombia (I.)[2]	0.076	0.285	0.095	0.270	0.453
Spain	0.234	0.219	0.179	0.249	0.0001
Mexico	0.140	0.276	0.096	0.230	0.131
Portugal	0.118	0.284	0.269	0.284	0.068
Women under-representation Item					
Argentina	0.139	0.339	0.146	0.349	0.850

Mexico	-0.023	0.304	0.028	0.293	0.433
Portugal	-0.069	0.303	0.132	0.261	0.001

[1] Bogotá, [2] Ibagué

In the GE item, there was a statistically significant main effect (less than 0.001), between the group of Science and Humanities and Non-Science only for Spain, where the group of Science showed the most adequate attitude. In fact, this group has shown the most adequate attitude of all countries. As regards the WU item, there were significant differences between the complete samples of Science and Non-Science in Portugal, where the group of Non-Science showed the most adequate attitude between the two of them. Concerning this item, the group of Science from Spain has shown a more adequate attitude.

Differences within the sample of Science

Among students

Taking as the unit of analysis the results on the issues, there is a significant difference only in the items of GE for students from Spain, where older students show a more appropriate attitude than young students. Table 2 shows GE and WU items where significant differences were found between the senior students (S2) and young students (S1), and where the attitude of the S2 group from the stated country was more appropriate.

Table 2. GE and WU sentences with significantly most appropriate attitudes of S2 group

Item/Sentence	A	B	C	D	F	G	H
GE	-	-	-	-	Spain	Argentina	Spain
WU	Brasil and Spain	Brasil, Colombia and Spain	Spain	Portugal	-	-	-

If we consider the GE item, no sentences were found where the attitudes of the S1 group from any country were more appropriate. With regard to the WU item, only in sentence "I" have we found a more appropriate attitude in a S1group, the group from Brazil. These results suggest that the only country where university studies prompt the construction of a more appropriate attitude by students towards the GE item is Spain (Argentina one sentence).

On the WU item, it is worrying that in Argentina and Mexico no significant differences among young and senior students were found. Moreover, we have only found improvements in a few sentences in other countries (again it seems that it is in Spain where university studies have the most positive impact).

Among teachers

Regarding the GE item, there is only a significant difference between in-service teachers (T2) and pre-service teachers (T1). In Brazil, the most adequate attitude is shown by the T1 group. Concerning the issue of WU, there is a significant difference in Argentina, it was the T1 group the one that showed a most adequate attitude.

With respect to the sentences in Table 3, there are GE and WU items where significant differences were found between in-service teachers (T2) and pre-service teachers (T1) and where the attitude of the T2 group from some countries has been shown more suitable.

Table 3. GE and WU sentences with significantly more appropriate attitudes T2 group

Item/Sentence	A	B	C	D	F
GE				Brasil	Brasil
WU	Argentina and Brasil	Arg. and Brasil	Arg. and Brasil		Brasil

Significant differences were found regarding the GE item, with most adequate attitudes by the T1 group in sentence C in Spain, and G and H sentences, in Brazil.

According to these results, the only country where there are differences with opposite variations in some sentences of GE items is Brazil, where the T1 group has a more adequate attitude on the item as a whole, but the T2 group has a higher index in sentences D and F. In Argentina and Brazil, the experience of teaching seems to improve teachers' attitudes toward the WU item (the same happens also in Spain, but regarding only one sentence).

Between women and men

Table 4 shows the countries where we have found significant differences between the views of men and women for GE and WU items, and women have shown a more adequate attitude than men have.

Table 4. Significant differences in GE and WU items

	More adequate attitude by women
GE	S1 Group Brasil, Students (S1 and S2) Portugal, T2 Group Mexico
WU	Total sample Spain, Argentina and Mexico, S1 Group Spain, S2 Groups Spain, Argentina and Brasil; T1Group Spain

On the responsibility of the school

In terms of the items which address the issue of WU, sentence E refers to the responsibility of the school in this situation. This sentence has only appeared in the list of those who obtained the most positive attitudes in Brazil. Because the surveyed population corresponds to the educational sector, it seems important to emphasize which were the groups that showed significant differences in this sentence; namely:

- The S2 groups from Spain and Portugal, and the T2 Group from Spain, where more adequate attitudes was shown by the Non-Science sample.
- The S1 group from Portugal and T2 group from Spain, where men's attitudes were more adequate than women's.

These results demonstrate that only the younger students from Portugal, the senior students of Non-Science from Spain and Portugal, the in-service teachers of Non-Science (particularly men) believe that schools have not done enough to encourage women to choose Science courses, even though women are as capable as men in Science.

CONCLUSIONS AND IMPLICATIONS

The results show that some naïve views about the relationship between women and Science still persist nowadays; furthermore, it is also noteworthy that students and teachers display somewhat different views. Positive attitudes have been detected towards the following issues:

- Equity between women and men in terms of what it is needed to be a good scientist
- The fact that differences in the way scientists work in Science are due to personal differences, regardless of gender
- The fact that men and women work equally in Science
- The fact that the causes for the number of males scientists being much higher than women scientists ARE NOT related to men being stronger, faster and more brilliant or have no difficulties in concentrating on studies
- The reason for which there are far more male scientists than female scientists IS NOT that men seem to be more scientifically capable than women

Some negative attitudes towards these issues still persist, for example in terms of the perceived differences between male scientists and female scientists, regarding how they do Science because:

- They do not work the same way
- They do not have the same studies
- Men and women have not the same IQ
- Men and women are not equal; they depend on the job they do.

In the European countries which were part of the PIEARCTS Project, as well as in Brazil and Mexico, the surveys show more positive attitudes towards the idea that the reason why there are more male scientists than female scientists is NOT because men are more interested in Science than women. It is evident that in these countries, there is an increasing awareness of the fact that Science is a social activity and is, therefore, the predominant ideas in society are influenced by this awareness. Few differences were found between senior undergraduates and young students; this seems to show that higher education is not contributing to improve the students´ attitudes regarding Gender Equity and Women under-representation in Science.

However, future female and male teachers from some countries (Brazil, Colombia and Spain) seem to be aware that women under-representation in Science is not a natural matter, but a situation caused by an androcentrist culture which has been perpetuated for centuries. Accepting this fact is the first step towards promoting a change in this situation.
Considering gender among the people in the educational area, it is possible to establish that women appear to be more aware than men of the fact that the relationship between women and Science is an unsolved issue. This is shown by the fact that the majority of the variables where differences have been significant between men and women, women are the ones who show more adequate attitudes. This is a positive sign because they can promote a change in attitude in the rest of the people they have an impact on (children, students, partners, etc.).

To conclude, we should engage in a serious and deep reflection about the role that schools have played in the reproduction of the distorted view of Science as neutral. The more positive attitudes about the responsibility of schools in having discouraged women from choosing Science courses have been shown by groups from Spain, Portugal and Brazil - which is a serious wake-up call for the rest of the American countries-, and mainly by young male students, male and female senior students and male and female teachers of Human and Social Sciences. It is striking to note that those more involved in Science education in primary schools were women, and in secondary schools and university it was Exact and Natural Sciences teachers.

"SCIENTIFIC INQUIRY PRACTICES OF WORKSHOP EXPERTS FOR ELEMENTARY STUDENTS IN MEXICO"

Reyes-C Flor[1] and Garritz Andoni[2]
[1] Universidad Pedagógica Nacional, Unidad Ajusco, EDUCIEN
[2] Universidad Nacional Autónoma de México, Facultad de Química, Departamento de Física y Química Teórica

Abstract: In this research, we characterize Scientific Inquiry practices of workshop experts for elementary students in Mexico in a teaching-learning science programme that provides scholar science and mathematics activities directed to children guided by a set of Workshop Experts, whose role is to head the workshops.

To characterize scientific inquiry practices, for four selected workshop experts, a session with children was recorder and analysed using *The National Science Foundation* (1999) teacher inquiry indicator's guide that look for special characteristics in the classroom.

This research shows that the Workshop Experts have evolved in their behaviour and actions, from a more participant and directive approach to an assessing and guiding role that involved listening and observing the student actions and interaction. The workshops experts aided with inquiry lesson materials and with a formation programme can produce a learning context that can be categorized by the indicators as inquiry based teaching and learning. It seem that with time, more formation's phases and experience immersed in an inquiry programme, inquiry actions can be performed by a teacher with better results.

Keywords: Scientific inquiry learning, elementary school, science teaching, inquiry indicators, inquiry practices.

BACKGROUND, FRAMEWORK, AND PURPOSE

Scientific inquiry is a concept that was presented for the first time in 1910 by John Dewey; since that time different educators have use it. For example, Joseph Schwab (1960, 1966) was an influential voice in establishing the view of science education through inquiry. He suggested that teachers should present science as inquiry and that students should use inquiry to learn science subject matter. To achieve these changes, Schwab recommended that science teachers should look first to the laboratory and use experiments to lead, rather than to follow, the theoretical classroom phase of science teaching.

In 1996 the National Research Council (NRC) presented a specific definition of inquiry, in which teachers can and should promote the curiosity and the development of the students' abilities regarding to inquiry. Inquiry is defined as:

> The diverse ways in which scientists study the natural world and propose explanations based on the evidence derived from their work. Inquiry also refers to the activities of students in which they develop knowledge and understanding of scientific ideas, as well as a comprehension of how scientists study the natural world (NRC, 1996: 23).

Anderson in 2007 emphasizes three inquiry subsections: scientific inquiry; inquiry learning; and inquiry teaching, explaining that if it is central to science learning then it must be central to teaching as well. This statement makes clear that there are three different subjects that can perform inquiry activities: scientists, the students and teachers.

In the last fifty years scientific inquiry has been a topic of interest in educational research mainly with the student as the principal subject but, according to Mac Neil and Krajcik (2008), there is a little amount of researches on the teachers' practices in inquiry classrooms. This research aimed to characterize Scientific Inquiry practices of workshop experts for elementary students in Mexico in a teaching-learning science programme.

THE ROLE OF THE TEACHER IN THE SCIENCE INQUIRY CLASSROOM

> A teacher, in order to guide an inquiry lesson must develop a robust capacity for pedagogical design, and the ability to put into practice a variety of personal and curricular resources to promote student learning. In Scientific Inquiry, the teacher´s role becomes less involved with direct teaching and more involved with modelling, guiding, facilitating, and continually assessing a collaborative student work. (NSF, 1999:82)

In an inquiry based teaching and learning the student and the teacher are expected to develop certain abilities related in each level to learning and teaching. The National Science Foundation (1999) adapted, form materials created by the Exploratorium institute for inquiry (2010), three different inquiry guides that look special characteristics in the classroom

1. What are the students doing? On-the-run reference guide to the nature of elementary science;
2. What is the teacher doing? The role of the teacher in the inquiry classroom;
3. How does the environment support inquiry? The social and emotional environment of the inquiry classroom.

Each one of them has an average of five activities and each activity present no less than three indicators.

The programme selected to performed this research is PAUTA (Programme Adopt a Talent: "*Programa Adopta Un TAlento*") created by the Mexican Academy of Sciences, in collaboration with the National Autonomous University of Mexico. This programme provides scholar science and mathematics workshops directed to children that are studying in elementary schools. In PAUTA there are Workshop Experts whose role is to head the workshops with students.

The programme, in a constructivist learning and teaching approach, pursues that children explore and analyse different phenomena by means of activities (Garcia *et al*, 2010), specifically designed to learn science by developing their scientific abilities. The activities, as was recommended by Schwab (1960), are arranged in sequences of the experimental type that allow students to review the concepts involved in a specific problem or question on different contexts.

Each activity has a document "expert workshop guide" with specific suggestions of actions and instructions that the teacher must perform to promote the children's development of science abilities in an inquiry activity context. According Martin-Hansen (2002) categories of inquiry, this is guided inquiry, in which the question to be solved is presented by the teacher and the student may decide how to approach it.

METHODS

Taking in account that the activities developed by the workshop experts are crucial tools with which teachers engage students in science as inquiry (Forbes & Davies, 2010) and by extension the pedagogical activities involved, the activity called "Floating and sinking" was selected to be examined; in this activity the children analyse how different objects can or cannot float.

The data collection was made primarily by videotaping the activity sessions of four workshop experts, in two main phases: the first semesters of 2008 and 2010. This four workshop experts were selected based on a previous research that aimed to document the Pedagogical Content Knowledge of the experts with a Content Representation frame of Loughran *et al.* (2004) that was applied all of the nine workshop experts. The selection of these four experts was made taking the next bases: That they wave participated in the previous research, the permanence in the programme, and finally the bachelor speciality: one was mathematic, one ethnology and two biologists.

The selection of the data collection corresponds to the two implementation of the same workshop, with the same four workshop experts, with students (from 6 to 13 years old) in the first year in the programme. It is important to mention that the programme have groups of student arranged by the levels that they have taken in the programme rather than the age that they have. The first time "Floating and sinking" took place was in 2008 and the next implementation with these characteristics was until 2010.

One video camera was used to film the actions of the workshop expert, and since two of them conducted each session, audio records were made for each one. For the analysis, the videotapes were coded with the indicators related to the activities in each one of the guides to observe inquiry activities. The present results have more emphasis on the analysis of the workshop experts' inquiry indicators.

RESULTS

We have found significant differences between the two periods (2008 and 2010). Regarding to the "Teachers Model Behaviors and Skills", in the 2010 workshop experts posse more scenarios to enhance that the student take control and responsibility on their action, whereas in the 2008 workshop experts did not promote this actions.

A clear evolution in the 2008 and the 2010 were fund related to "Teachers Use Multiple Means of Assessment" and "Teachers Act as Facilitators", mainly the workshop experts in 2010 listen more often and talk or direct much less to the student, the conversation held in the classroom in 2010 evidence that the Expert is listening carefully to the children and using that as basic information to express the next idea or comment only if necessary.

> 2010 Student 1: We weight the wooden cylinder, the wooden cylinder floats but it was lighter. And the spoon, [the metal spoon] well the spoon is lighter than the cylinder. But, the cylinder is…well…
> Workshop expert: ¿Which cylinder? [The metal one or the wooden one]
> Student 2: The metal spoon is heavier; it is one gram heavier than the wooden cylinder
> Student 1: But the cylinder was heavier, was not it? Or was it? [Student2 y Student3 confirm that the cylinder was heavier]
> The cylinder was heavier than the spoon, it [the cylinder] did not sink and the spoon did.
> Workshop expert: What can you say about this?

> Student 1: Well, I think it is the material.

Whereas in 2008 there are several interactions that clearly show that the expert did no listen to the student, that they try to impose a particular question that is different than the actual interest of the students, and that they show up to student discussion an posse a new question, before listening to what they have been arguing.

> 2008 Workshop expert: Which one of the objects that you have is going to sink?
> Student 1: The iron one
> Workshop expert: that is right the metal cylinder
> Workshop expert: Which other?
> Workshop expert: over here they said that the wooden cylinder. Why do you believe that this one is going to sink? It is because it is heavy, right?

Also the Workshop Experts in 2010 started to suggest new things to look at and try, and encourage further experimentation and thinking in their students but in 2008 they followed the facilitator guide in a more rigid way.

CONCLUSIONS AND IMPLICATIONS

This research shows that the Workshop Experts have evolved in their behaviour and actions, from a more participant and directive approach to an assessing and guiding role that involved listening and observing the student actions and interaction. In this guiding role they suggest more often new things to look at and try, and thinking: This could be related to the novelty of the activities and the use of inquiry based activities in 2008 and to the expertise gained though the coupled of year in the programme. It seem that with time, more formation and experience immersed in an inquiry programme, inquiry actions can be performed by teacher with more emphasis and probably with more clarity on the goal pursued in each one.

The workshops experts aided with inquiry lesson materials and their regular formation courses can produce a learning context that can be categorized by the indicators as Inquiry based teaching and learning.

As a corollary all changes involved a considerable amount of energy, work and commitment; specially changing the pedagogical skills, but building them is equally important to the construction of content knowledge, particularly as a means of providing student-centred learning experiences.

And in a metacognitive level, to improve the science teaching-learning process, it is important to document what happened in an actual Workshop, how Workshop Experts establish didactic units with these characteristics, and how they promote the development of scientific abilities in their students.

ACKNOWLEDGEMENTS

This research was supported by “Instituto de Ciencia y Tecnología del Distrito Federal” with a scholarship given to Flor Reyes-C. The authors wish also to thank “Programa Adopte un Talento” for the facilities given to conduct the research.

EPISTEMIC STYLES OF THINKING OF PRE-SERVICE CHEMISTRY AND PHYSICS TEACHERS

Norman Riehs and Stefan Rumann[1]

[1]University of Duisburg-Essen, Germany

Abstract: Theoretical works of different authors lead to the assumption that the subject of study influences the epistemological stances of students. Regarding pre-service teachers, views on aspects of Nature of Science can differ between biology, physics, and chemistry teachers. Due to the lack of quantitative instruments examining epistemological stances in respect of scientific realism, a questionnaire was developed and carried out in a pilot study to pre-service secondary physics and chemistry teachers in a pilot study (students and Ph.D. students; n = 41).

The results of the pilot study are insightful. The chosen items are comprehensible and show a good reliability. The size of the sample admits of item response theory (IRT) calibration, showing the items fit the model adequately. As a first result, the difference of the degree of scientific realism of pre-service chemistry and physics teachers is significant and the effect size is huge. Chemistry teachers tend more to scientific realism than physics teachers. The degree of scientific realism scale might be useful for explaining the classroom handling with models and modelling of science teachers by epistemological positions.

Keywords: Nature of Science, Philosophy of Science, Secondary Teacher Education, Chemistry, Physics

THEORETICAL FRAMEWORK

In the past decades philosophers of science have argued whether or not philosophical stances of scientists influence their work (see McMullin, 1984, Scerri, 2000; Elfin *et al*., 1999). Additionally, the relationship between specific subjects and epistemic positions has not yet been pointed out. But despite this lack of quantitative research one can find some evidence for different 'styles of thinking' in the history of science. This concept was first developed in the early 20th century by Ludwig Fleck and continued by Alistair Crombie and Ian Hacking (see Bensaude-Vincent, 2009). Bensaude-Vincent used the term 'styles of thinking' for an analysis of the chemists' approach to science. In a similar way Eisvogel (1994) examined the character of a theory as either 'realistic' or 'instrumentalistic'. These characters form the thinking among the community of scientists using these theories.

Independent of the question whether there is an impact of philosophical stances on applied scientists' thinking and acting, there is much more interest for research in science education regarding the relationship of epistemology of science teachers and their handling of models and students' beliefs in educational situations.

In spite of increasing calls to implement Nature of Science (NoS) in the science curricula (Lederman *et al.*, 2002), quantitative studies to point out science teachers' epistemic stances and their influence on aspect of pedagogical content knowledge (PCK) have not yet been carried out.

The first criticism on stated NoS-tenets in science education was given by Alters (1997), examining the difficulties of philosophers and scientists with the goals of NoS-programs.

Although there was a dispute about the design of Alters' survey, the criticism on stated tenets cannot be overlooked: philosophy does not give absolute and final answers. In contrast Lederman et al. (2002) argued for the emergence of consensus on the tenets with increasing the level of generality. This position can also be found in earlier works, like Abd-El-Khalick et al. (1998). But following up the path of generality regarding epistemic assumptions leads to the meta-level of objectivity and subjectivity of science, or–in general parlance–to the question whether an objective and independent outer world exists or not. Basic assumptions determine the stances in the lower levels, e.g. one cannot be sure about the factual existence of non-observable entities without claiming a world independent of the observer.

To respect the different views on the world it is necessary to change the tenets into open questions, which was first suggested by Clough. For instance, instead of teaching the tenet "scientific knowledge is tentative" one should rather discuss with the students the question "in what sense is scientific knowledge tentative?" (Clough, 2007).

This study is concerned with the question whether or not the styles of thinking of chemistry and physics student differ in respect of the degree of scientific realism. It is supposed that a more anti-realistic epistemic position of student teachers regarding the reference of scientific theories and entities allows them easily to switch between students preconceptions driven by common-sense-realism and mature scientific concepts.

Due to some evidence from the literature (e.g. Scerri, 2000; Bensaude-Vincent, 2009), it is expected that the more anti-realistic stances will be found within the physics teachers group, while the chemistry teachers share a more realistic view on the world.

METHODS

To examine the epistemological positions of chemistry and physics student teachers a questionnaire was developed and carried out in a pilot study to measure the degree of scientific realism. The theoretical framework for the categorisation of the different thinking styles was based on philosophy of science literature (Hacking, 1983; Van Fraassen, 1980; Putnam, 1975).

The idea of a 'degree of scientific realism' scale bases on the assumption, that each position in philosophy of science has its own authority, but all positions share a more or less realistic approach. The aim of the questionnaire is to examine a one-dimensional scale to describe the degree of scientific realism of science teachers.

20 statements about scientific realism or anti-realism were collected from philosophy of science literature, followed by a translation into non-philosophical language. Pilot study participants' agreement regarding the given statements was measured by a four-step Likert-type scale from "I totally agree" to "I totally disagree". The statements derived from philosophy of science literature were verified in terms of the comprehensibility through the participants' option to leave the item out, if they did not understand the arguments' meaning.

RESULTS

The pilot study was conducted with a sample of 41 pre-service chemistry and physics teachers, 20 student teachers at the end of their study and 21 Ph.D. students of science education. The respondents' demographic data is presented in table 1.

Table 1: Respondents' demographic data.

Variable		Sample Size
Total		41
Level of education	*Students*	21
	Ph.D. students	20
Subject of study	*Chemistry*	23
	Physics	18
Sex	*Female*	18
	Male	23

Following Linacre (1994) the sample size suffices for partial credit model (PCM) item calibration, which was made with R-statistics. The analysis examined a mean item-infit-MNSQ of 0.99 (S.D.: 0.25; range: 0.56–1.43) and a mean item-outfit-MNSQ of 1.04 (S.D.: 0.26; range: 0.56–1.50). The values show the productivity for measurement (Linacre, 2002). The PCM item measures are sufficiently distributed with mean modelled standard errors of 0.21 (S.D.: 0.02). The items' difficulty spread is between −1.81 and 1.19 logits, the spread of respondents' measures spans from −2.24 to 0.85 logits on the person–item map. In the further analysis the PCM measures will be used instead of the persons' raw scores.

A Shapiro-Wilk test (Shapiro & Wilk, 1965) verifies the participants' measures come from a normally distributed population. The thesis of a non-normal distribution is refused ($p = 0.45$). Further tests including subgroups “physics” and “chemistry” show quite similar results ($0.42 < p < 0.49$).

One major finding is the significant difference in the degree of scientific realism between the subgroups of pre-service chemistry and physics teachers (table 2). The effect size of the difference is huge (Cohen's $d = 1.24$).

Table 2: Degree of scientific realism mean measures of pre-service chemistry and physics teachers.

Subject of study	Measure	S.D.	T	p-value
Chemistry	0.13	0.68	3.90	< 0.01
Physics	-0.80	0.81		

CONCLUSION & IMPLICATIONS

There has not been collected enough data yet for verified conclusions. Nevertheless, if Nature of Science should be part of science education, one has to rethink teachers' education in respect to the philosophy of science. The very creating of new chapters for textbooks and enlarging or substituting of curricula is not an adequate form of implementing the philosophical area of Nature of Science in secondary school education. The development of a deeper understanding of the philosophical debate might be a key skill for science teachers in respect of analysing and understanding students' misconceptions. To answer this question, the questionnaire will be used with a larger sample, combined with quantitative instruments to measure the use of models in classroom contexts.

NOS IDEAS AS CNTEXTUALIZED IN THE PRESENT SCIENCE: NANOMODELLING AS AN EXAMPLE

Suvi Tala[1]
[1]Department of Physics, University of Helsinki

Abstract: Understanding nature of science (NOS) is widely considered an important educational objective and views of NOS are closely linked to science teaching and learning. Nowadays, there is a kind of consensus about the content of NOS teaching, which is a result of analyses in educational, philosophical, sociological and historical research. This consensus content is listed as statements of science, which students are supposed to understand during their education. Research in science education has anyway frequently shown that students have not reached sufficient understanding about NOS. The reason is proposed to be that the formal statements about nature of science and scientific knowledge can really be understood only as contextualized in the practices of science. To contextualize NOS statements in the actual practices of science in contemporary education, we need empirical studies, which are performed in co-operation with scientists themselves. This is such a study; by employing both a questionnaire and interview as research methods this study reveals how practicing nanoscientists perceive the nature of science developed in their own research projects. Many of the general NOS statements arise as contextualized in discussion with practicing scientists; deepening thereby our understanding about the core of NOS, science and scientific knowledge, for science education. The results can be used also as such, as a basis of reflective stories of recent science for contextualized NOS teaching – and the method developed can be used as a basis of "interview a scientist" tasks and in further research. For the contextualized NOS education suggested in this paper, we would need several similar empirical studies.

Keywords: contextualized NOS, NOS education, scientific modeling, contextualized interview study

NOS CAN BE UNDERSTOOD AS CONTEXTUALIZED IN EXAMPLES OF SCIENTIFIC RESEARCH

Developing an adequate understanding regarding the nature of science (NOS) in students has been widely seen at the core of the scientific literacy (Matthews 1998, McComas & Olson 1998). Indeed, understanding the nature and the basis of what one is studying encompasses coherent conceptualization and conceptual understanding (Osborne et al. 2003, Sandoval 2005) – the traditionally valued goal of science education. Understanding about science and its nature increases then one's interest in science and science classes. At the moment, there is a kind of consensus on what the NOS understanding does include; this is a result of analyses of educational, philosophical, sociological and historical research and discussion (Lederman et al. 2002, Mathews 1998, McComas & Olson 1998, Osborne et al. 2003). Such NOS content is defined by listing statements of nature of science, which students are supposed to learn during their education – or as family resemblances (Irzik & Nola 2010). Because science is rich and dynamic endeavour and scientific disciplines are quite varied, the NOS statements are quite general descriptions about "science". For example, the statements "models and modelling have important roles in science" and "science has an impact on technology and technology has a role in science" appear frequently on the lists of NOS statements. These general NOS statements can be interpreted in a numerous ways: for example, the viewpoints guiding scientists' research practices is the viewpoint supporting their concept building and the understanding about the scientific process.

Irrespective of the century-long history of the place of NOS in many curricula (Lederman et al. 2002, McComas & Olson 1998, Mathews 1998), the NOS objectives – learning the NOS statements for understanding – have not been reached (see e.g. Clough 2011, Lederman et al. 2002, McComas & Olson 1998, Osborne et al. 2003 and the references therein).The situation is considered to be the result of the taken-for-granted explicit and abstract view towards NOS (Lederman et al. 2002, Sandoval 2005). One can understand the abstract NOS themes only as contextualized into different contexts of scientific research; but students do not know what scientists do while working. Thus, students have to become familiar with authentic examples of scientific research, which provides them with contexts to understand the abstract NOS themes. Research indicates that by this kind of reflective – or contextualized – approach to NOS education, good results can be reached (Clough 2011, Hanuscin, Akerson & Phillipson-Mower 2006, Matthews 1998, Sandoval 2005). Moreover, when opening this kind an insight to the production of scientific knowledge, NOS teaching increases the coherence of science education. Thus, what is needed to enhance NOS understanding in science education is concretizing by examples what the NOS statements mean in the practices of science in different fields of research.

At the moment there are rich examples of contextualization in historical stories of science (e.g. Clough 2011). This study suggests that in order to support understanding about the present science for literacy, which means an ability to apply one's NOS understanding in public discussion about contemporary science, also examples of what does NOS ideas mean in the context of contemporary science need to be addressed. Discussing the present science in science classes may also increase students' motivation to study NOS and science in general. Anyway there is a lack of empirical studies about the nature of science in the contemporary knowledge construction practices of science and scientists' ideas about the nature of science they do. Thus, here is provided such an empirical study, as an exemplary case, a study about the nature of science as seen through the practices of nanoscience. The study examined how the viewpoints opened by NOS statements to scientific knowledge construction and justification may do appear in the nanoscientists' views. The contextualized method was developed and employed in order to increase the validity: simple, the scientists were not asked what nice ideas they would like to be told in education about the nature of their field, but instead to encourage them to tell about the nature of their field at the practical level. Thus, the study provides exemplary cases, by which to understand the NOS themes in the practices of science. The abstract NOS ideas can be better understood by listening to such exemplary voices in the mixed choir of scientists.

NOS LISTS AND DIFFERENT METHODS OF SCIENCE

The nature of science is in the lists of NOS ideas defined from the viewpoint, how natural science differs from the humanities, for example: thus, the general definitions of science, such as listed by Merton norms (objectivity etc.) or counter-norms, are not listed. The table 1 presents a summary of the typical NOS ideas appearing on NOS lists, as it was summarized on basis of previous comparisons and studies (Hanuscin, Akerson & Phillipson-Mower 2006, Lederman et al. 2002, McComas & Olson 1998, Osborne et al. 2003, Sandoval 2005).

- *"science is an attempt to explain natural phenomena"*
- *"there is no one scientific method", but "a variety of scientific methods is employed"*
- *"models and modelling have important roles in science"*
- *"science has an impact on technology and technology has a role in science"*
- *"the creative role of human beings, societies and cultures in constructing science"*
- *"the historical development of science"*
- *"the impact of science on cultures and societies"*
- *"science is essentially a global phenomenon having both global and local influence"*
- *"certainty or tentativity of scientific knowledge"*
- *"theory-ladenness of experimentation"*

Fig1: *A list of the typical NOS objectives*

The natural sciences become first and foremost defined by the objectives adopted and methods employed: The shared motive of the different natural scientists is an attempt to explain "natural" phenomena (NOS theme) taking place in natural and man-made environments. In that is used a variety of methods (NOS theme). Indeed, the nature of scientists' knowledge building and the nature of the knowledge produced in that are strongly figured out by the methods used. The methodologies employed in revealing reality can be divided into theoreticians', modellers' and experimenters' fields of business; the different practitioners' can see the nature of science in a quite similar way but they explain the nature of this enterprise from different viewpoints. In science studies, most analysed are the theoreticians' viewpoints and the viewpoints opened by theory-oriented approaches. For about a half decade attention has been increasingly paid also on experimentation and experimenters' viewpoints (see Tala 2009 and references therein). Only recently, when modelling is noticed to be rapidly growing, as the third method of science beside the traditional ones, there has been a growing interest toward it in science studies (e.g. Humphreys 2004, Morrison and Morgan 1999). Then has been noticed also the lack of empirical studies considering the practices of modelling and viewpoints opened by practising modellers. Because modelling is nowadays widely used by side of the traditional methods, modelling will probably be soon described by more details also in the lists of NOS statements (like the traditional methods are in the present lists).

In science education models are typically seen as deduced from theories and modelling as a direct continuation of theorizing, which reflects the situation in the science studies couple of decades ago. The discussion about models in science studies during the last decades in science studies, has given them a variety of roles, but it have been generally agreed that models are representations (see e.g., Giere 2004, Hughes 1997, Morrison and Morgan 1999): we gain knowledge from models because they represent target objects in the world in some relevant respects. Moreover, recent studies (e.g., Galison 1997, Hacking 1983, Humphreys 2004, Morrison & Morgan 1999) indicate that the perspective on the practices of science provides a different approach to models and modelling; models and modelling have been suggested to have quite an independent role as mediators between different methods (e.g. Morrison & Morgan 1999). These questions of how the relations between reality and the different methods employed are constructed are important for scientists (Hacking 1983; Galison 1997) – and it is important for science education as a base of the knowledge taught. Thus, in order to understand better the nature of this enterprise called science, it is worth for to ask also practising scientists how those links with reality – or realities – and different methods are constructed in their knowledge building

METHODS: QUESTIONNAIRE AND INTERVIEWS AS CONTEXTUALIZED IN THE INTERVIEWERS' PROJECTS

The phenomenological case study (Tala 2011) taken here as an example, discovers the conceptions and beliefs of nature of science guiding the knowledge building practices of nanoscientists – and teaching these practices in their doctoral education. The informants are Finnish material physicists studying nanophenomena by realistic simulations, 5 experts (E) and 5 apprentices (PhDs; A). The research was planned in co-operation between researchers' in science education, in physics and in philosophy. To get a broader view, the views of the informants were studied by multidimensional methods: The informants answered a written questionnaire about their epistemological and methodological views as contextualized in their on-going projects. The questionnaire was planned on basis of understanding opened by recent science studies and familiarity with the practices of physics – this basis also helped in contextualizing the study in the interviewers' research projects.

The NOS views are many time tested by asking scientists questions at general level, asking such questions as "what you think are the most important points every citizen should know about the nature of science?" or "do you think models play a role in science"? Anyway, many physicists do not like to speak "philosophically": although they deal with contextualized philosophical questions in their work, they do not need to think the philosophical question at the general, explicit level while working. Indeed, there is always a possibility that the interviewer and the interviewee understood the general terms in different ways. Moreover, when the questions or answers are contextualized in the informants' concrete doings, in this case in their on-going research projects, they may tell what really guides their action and decision making, rather than what theoretical lessons they may have learned about it, for example.

The informants were interviewed one by one; the interviews were semi-structured on the basis of the interviewees' responses to the questionnaire and their articles they sent in advance. It was noticed that the same viewpoints emerged over and over again in the responses of the internationally successful scientists, increasing the reliability of the results. The transcript interviews together with the responses to the questionnaire were analyzed by qualitative content analysis: the NOS statements formed the categories used and then also the links existing between the contextualized NOS statements were noticed. The interviewees checked the analysis; as a consequence, the interpretations became corrected according to the interviewers' requests (validity).

RESULTS: NOS AS ONTEXTUALIZED THROUGH THE VIEWS OF PRACTISING MODELERS

Many of the shared NOS ideas arise in the interviews with practicing nanomodellers, as contextualized in their projects (particular definitions of NOS). This kind of contextual approach also clarifies how the NOS statements are closely connected to each others in authentic research processes, which will be seen in the following examples picked out from the results. Every field of science highlight and explain more some NOS ideas than others. Because the modellers' views are under scrutiny in the following, the statements 'science has an impact on technology and technology has a role in science' and 'models and modelling have important roles in science' become naturally emphasized.

Basically, the expert nanomodellers define their field of research to be "application-motivated basic research" (E1), which they explained means that possible applications – potential technological, financial and human needs – make selections between the possible research projects before launching one. They do not develop commercial nano-products[1], but for financial reasons, for example, those interesting research topics are selected, which have "relevance of some practice" (E1). In particularly an apprentice reasoned his research by "tree words: nano, bio, medi" (A1). The interviews told that they clearly refer to the applications, when writing the applications for financial funding or introductory parts of their publications or telling about their research for general public. At the same time nanoapplications, impose new ethical problems – for example, the interactions of nanoparticles in a human body, are not known yet – and become limited on this basis. Nevertheless, the interviewers highlighted that the applications "are [only] in the back of my mind" (E2) and thus they consider that they do not need to consider the ethical questions related to the possible applications. Thus this strive for applications contextualizes in a way not only the NOS statement 'science has an impact on technology' but also the pair of NOS statements 'science is a product of a large social and cultural settings' and 'science has an impact on cultures and societies'.

Furthermore, technology provides an access to the artefactual nanoworld: when working, modellers sit mostly by their computers. No one of the interviewers failed to mention how computational and technological abilities, namely the capability of computers figures out what can be studied by nanomodelling, and how. The fundamental reason is concentrated in the following novice's response: "the whole of molecular dynamics [the favoured method] would not function if the frequently repeated calculations were not made as simple as possible and quick for the computer to calculate" (A2). As a consequence, what can be studied and how it is studied in nanophysics is strongly figured out by technological limits, namely by the capability of computers. Nowadays, the length of the objects simulated at the nanolevel has to be limited to some nanometers, or, alternatively, an event on the surface seen by a nagged eye can typically be simulated only for a nanosecond. Nanoscientists are creative (NOS theme) when discovering the nanoworld within these limitations of time and length scale.

But the modelling technology, and especially computational power, is a rapidly developing field, advanced as collaboration between scientists and technologists. A century ago, nanoscientists did not have the kind of inside to the reality of physics they develop and maintain nowadays. The development is not going to stop here; with a great pleasure, the interviewees described what they can study in the nanoworld, when computers develop on. In this way, also the NOS theme 'the historical development of scientific knowledge', is easier to understand by considering a concrete development of technological capability.

As a new field of study, nanoscience is a rich example of how science develops by correcting and extending the previously "known" and the scope of this knowledge: at the time, when the most of the basic scientific content presented in the high school text books where discovered, the nanoworld was entirely unexplored.[2] In due to the dreams of the future development, in

[1] The applications of nanotechnoscience, ranging from smart drugs to environmental materials with extraordinary properties and to fast processing, ultra thin, flexible machines (see also, Rosei 2004), improve many ordinary artefacts.

[2] The recent history explains also the contemporary science: For example, scientists did not have access to the nanoworld and nanophenomena before the invention of the scanning tunnelling microscope by Gerd Binnig and Heinrich Rohrer at IBM Zurich Research Laboratory, for which they received the Nobel prize in physics in 1986. The scanning tunnelling microscope is an instrument for imaging surfaces at the atomic level, which is nowadays an everyday device in laboratories, it is employed also by those interviewers who have experience of working on the experimental side of the field. Additionally, the discovery of fullerenes in 1985 by Harry Kroto, Richard Smalley, and Robert Curl (Nobel prize in chemistry) was important for the foundation of nanoscientific research.

addition to the development of computers' calculation power allowing the increase in the size and time of the simulations, the modellers mentioned also their expectations concerning the development of experimental technology: according to a novice, at best this would mean the "real-time measuring equipment"(A3) (like a video camera). At the moment they observe the situation like in-direct still photos and numbers linked to those. But then, "these models are naturally quite simple, and thus do not represent a system very well"(A2). The more advanced a interviewed scientist is the more (s)he seems to highlight the role of technology figuring out the scientific modelling. Then an expert pointed out: "when a physical template [the mathematical formulation of physical law] is fitted to a computer, it becomes a kind of new theory...[it] is never the same as the original physical template which provided the starting point."(E3) In consequence, the NOS idea 'science has an impact on technology and technology has a role in science' is quite a deep one: the science-technology relationship should be understood to strongly figure out both activities to the extend it alters the basis of knowing in both fields, the epistemologies employed. Finally, even the interviewers' modelling is called "the realistic modelling", such successful modelling is guided by an instrumental view towards models and modelling, as seen in the following.

In nanomodelling is generated new knowledge of the previously unknown phenomena under limited possibility for experimentation: this is generative modelling. In practice the modellers make a coarse model, which then become fitted with experimentation. In that fitting, modelling figures out the experimentation from the planning of the experimental settings to the interpretation of them. But then it is a two-way process: also modelling becomes fitted to experimentation, and validated by this fitting with experimentation. This is what the NOS statements 'the empirical base of science' and 'experimentation is theory-laden' mean in the case of the practices of nanophysics. Nevertheless, even the development of modelling and experimentation take place in close interaction, those remain as separate approaches. The modellers emphasize this to the extent that "a model doesn't care about the actual conditions or claims that it explains them, since the only important property of a model is its functionality"(A4). In consequence, the modelling, which mediates between theory and experimentation, advance both limited traditional methods, experimentation and theorizing, staying anyway an independent approach.

It was notices in this study that young scientists adopt these above introduced contextualized views about NOS in their field during their education. For example, young modellers start to understand, how technology both enables and limits research projects, and how it figures out the scientific knowledge construction and justification processes. The results indicate that the longer a successful young modeller has worked for a research group, the nearer her/his contextualized NOS view are the elder researchers' views. Thus, the view opened by this empirical study seems to reflect the view, which guides scientists in successful knowledge building. As such, it deepens our views about the nature of science, by the viewpoints supporting conceptual understanding and understanding about the scientific process.

CONCLUSIONS AND IMPLICATIONS

This study showed how many of the general NOS notions arise as contextualized in discussion with practicing scientists. Understanding the practitioners' contextualized NOS views deepens our view to science for science education. Especially, the results of this empirical study extend recent views of the quickly developing nature and roles of modelling, simulation and modelling technology in science – and theirs relation to experimentation and theories. In science classes the understanding of the nature of science listed as NOS statements, can be improved by providing examples of contemporary science, constructed on the basis of *empirical studies* like this.

The empirical base provided by the study on nanomodellers' views can be used as such, for example, as picking up case stories from the data, providing concrete meaning into the abstract and general NOS notions in science education. Because the study was contextualized in the interviewers' research projects, there in the interview data exist many practical examples of the kind of knowledge building described here and, because those are in the field of realistic modelling, many of them could be introduced also at the level of compulsory education as examples of this kind of way of thinking. In order to make NOS teaching by contextualization effective, the stories and their relation to the school science activities have to be also discussed in science classes; good learning results have been reached by reflective approaches to NOS, and by approaches combining the implicit and explicit NOS teaching (Hanuscin, Akerson & Phillipson-Mower 2006, Sandoval 2005). Indeed, different fields of science highlight different viewpoints to the nature of science. In order to extend the base of examples in contemporary science, we need more empirical studies performed on different fields of science.

Abstract: The understanding of the nature of science (NoS) is assessed in a large sample of high-school science teachers, which encompasses pre-service and in-service teachers. The teachers anonymously completed 15 questions, whose responses are scaled into a set of attitudinal indices. The results show global neutral attitudes of teachers, and the detailed examination of indices identifies the teachers' strengths and weaknesses beliefs; unlike other studies, which provide a negative profile of teacher understanding, the diagnosis that emerges is more complex, as appropriate beliefs coexist with some inappropriate beliefs; however, the overall assessment must be negative, because the science teachers should exhibit better understanding of these issues. The pre-service science teachers do not significantly differ from in-service science teachers, so the evidence is not decisive to claim that science teaching practice contributes to improve NoS understanding. These results suggest the urgent need to update initial and in-service training for science teachers, to improve their understanding of NoS topics in science curricula, and thus improve science teaching. The implications of the methodology and results for the research, teacher training, and teaching of nature of science and technology issues are discussed.

Keywords: nature of science, science-technology-society, evaluation of conceptions, teachers' thinking, teacher training.

BACKGROUND, FRAMEWORK, AND PURPOSE

The nature of science (NoS) is widely accepted today as an undisputable target of science education to achieve an authentic scientific and technological literacy for all. Understanding NoS is deemed the most innovative goal of science education and an important component of scientific literacy for all. Thus, the school science curriculum should incorporate and the teachers should teach them (e.g., Abd-El-Khalick & Lederman, 2000; Lederman, 1992).

Research on NoS consistently reports that pre-service and in-service science teachers' understanding of NoS issues widely deviate from the modern views of science, as the history, philosophy, and sociology of science and technology studies have currently set up. Rather it seems close to traditional, positivist (logical empiricist), and idealistic views of S&T, which are similar to the list of myths (McComas, 1996), or contrary to the list of consensuses (Bartholomew, Osborne & Ratcliffe, 2004). Many of the research show that teachers understand science as a static body of knowledge (thus, true and unchangeable), or as a process of discovering what is out there, not as a human process of inventing explanations, and so on (among others, see a recent revision of state of art in Lederman, 2007).

Teachers' NoS beliefs are central for science education, because they decisively influence their teaching practices within the classrooms. For instance, teachers who belief that science is an accumulation of knowledge tend to do experiments by following the textbook instructions and getting the right answers; in contrast, teachers who belief that science changes are more likely to encourage students' discussions (Smith & Scharmann, 1999). Besides, some studies pointed out that teachers with adequate NoS understanding do not automatically and necessarily teach NoS issues into classroom (Lederman, 2007). Although there are many factors involved in the decisions to teach NoS, in general, teachers lack relevant pedagogical skills to this aim. Further, research points out that some teaching practices are key to adequately address curriculum NoS issues: planning, designing and assessing the NoS contents, supply explicit adequate NoS concepts to learners, and providing general reflection and coherence between NoS tenets and the representations of science and technology within the classroom (Lederman, 2007).

RATIONALE

Scarce research on teachers' conceptions about NoS has been focused on non-Anglo, in-service teachers until recently. So this paper draws data from an international cooperative investigation (Iberian-American Project of Evaluation of Attitudes Related to Science, Technology and Society, Spanish acronym PIEARCTS) that diagnose the NoS beliefs across seven Iberian-American Spanish and Portuguese-speaking countries. This paper presents the results of the application of the new PIEARCTS methodology to assess the NoS conceptions of large teacher sample that include pre-service and in-service high-school science teachers. The NoS conceptions are posed here from a wide perspective that includes internal aspects of science (philosophy and sociology of science) and external aspects of science (relationships of science with technology and society). The paper search empirical answers to the questions: Which are the strengths and weaknesses of teachers thinking on NoS? Do practitioner science teachers' understand NoS better or worst than their pre-service counterpart?

METHODS

Sample

The participants are 613 high-school science teachers, about one third (32%) in-service teachers and two third (68%) pre-service teachers. pre-service teachers in Spain are university graduate students in STEM specialties (physics, chemistry, biology…), who are involved in a postgraduate diploma in science education to be credited as prospective teachers (without educational experience); the in-service teachers are practitioner teachers. Their age range from 23 to 63 years and the sample splits approximately in equal halves by sex (52% men).

Instrument

The Questionnaire of Opinions on Science, Technology and Society (Spanish acronym, COCTS) is an adaptation into Spanish language and culture of the VOSTS and TBA-STS (Aikenhead & Ryan, 1992; Rubba, Schoneweg & Harkness, 1996). The COCTS is an empirically developed pool of 100 multiple-choice items, which inherits the credit of VOSTS and TBA-STS, as one of the best paper and pencil instruments to evaluate NoS&T beliefs (the empirical development of items warrants the item validity). All items display a common format: the stem presents a specific NoS issue, using a non-technical, familiar and simple language. A changeable number of sentences, each labelled with a letter A, B, C…, follow the stem; each sentence states a rationale position (belief) on the stem issue (Vázquez, Manassero & Acevedo, 2006).

The research team consensually selected 30 items that were distributed into two 15-item paper and pencil research booklets (F1 and F2; see table below), which meet a balanced coverage of the different issues. Each participant answered one randomly assigned form (F1 or F2), with roughly a half of the participants answering the Form 1 (309), and the Form 2 (304).

Table 1. Labels of the questions included in the two questionnaire forms (Form 1 and Form 2) across the structural dimensions of NoS issues. A short description of the question issue follows each key number.

Dimensions	Form 1 Items (key / issue)	Form 2 Items (key / issue)
a) Definition of S&T	F1_10111 science	F2_10211 technology
	F1_10411 interdependence	F2_10421 interdependence quality of life
b) STS Interactions	F1_30111 STS interaction	
Influence of society in S&T	F1_20141 country's government policies	F2_20211 industry
	F1_20411 ethics	F2_20511 educational institutions
Influence of S&T in society	F1_40161 social responsibility contamination	F2_40131 social responsibility information
	F1_40221 moral decisions	F2_40211 social decisions
	F1_40531 life welfare	F2_40421 Application to daily life
		F2_50111 union two cultures
Internal Sociology of science	F1_60111 motivations	F2_60521 gender equity
	F1_60611 women under representation	F2_70211 scientific decisions
	F1_70231 consensus decisions	F2_70711 national influences
	F1_80131 advantages for society	
c) Epistemology	F1_90211 scientific models	F2_90111 observations
	F1_90411 tentativeness	F2_90311 classification schemes
	F1_90621 scientific method	F2_90521 role of assumptions
		F2_91011 epistemological status

Procedures

The respondents rate their agreement (1, total disagreement; 9, total agreement) on each sentence of the items. These sentence scores are scaled into quantitative indices (-1, +1), whose meaning is invariant across all sentences: the higher (lower) the index score, the higher (lower) the belief's correctness according to the current knowledge from history, philosophy and sociology of S&T (Vázquez & Manassero, 1999; Vázquez et al. 2006). Averaging the sentence indices within each item, four new indices are produced: three indices for the three groups of sentences (categories) and one global index for the whole item. Thus, this scheme describes the teacher's through on NoS through over one hundred and fifty invariant indices (sentence, category and item indices). The index scores allow the use of inferential statistics for hypothesis testing, which can be applied to compare groups (pre-service vs. in-service teachers), or to set up cutting points for identifying the strengths (highest positive), weaknesses (lowest negative), and neutral beliefs (Vázquez, Manassero & Acevedo, 2006). The criteria to achieve relevance are the statistical significance ($p < .001$), and the effect size of the differences (differences measured in standard deviation units; $d > .30$).

RESULTS

The diagnostic methodology evaluates each item through a set of variables that includes the sentence indices, the three category average indices, and the overall item index (average of the three categories). The grand mean of the item indices for all teacher sample are slightly different for the form 1 (m =.1862; DE = .5456) and for the form 2 (m = .0809; DE = .5531); both are positive, but quite close to the null value. This result can be interpreted as a indicating neutral though somewhat positive conceptions towards NoS issues; some positive indices compensate the negative ones to produce this approximately neutral value for the global mean of the entire sample, which suggests that informed beliefs coexist with other less informed beliefs.

Teachers’ strengths and weaknesses

The distribution of the average item indices is displayed in figure 1 and 2 for both forms (F1 and F2). Both figures show asymmetrical distributions, where most of items are placed in the positive area (F1 that has only one item in the negative area of item index scores.

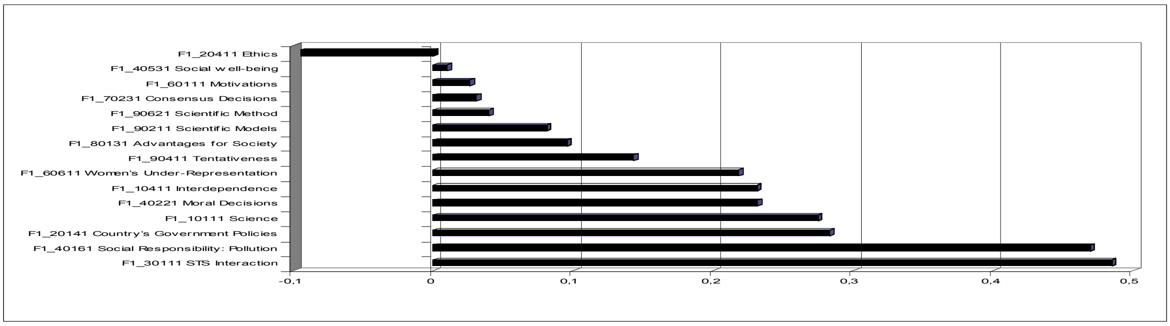

Figure 1. Average item indices for the 15 questions of the Form 1.

The items with the highest positive indices (more than one standard deviation above zero) identify the teachers’ strengths and weaknesses. The list of F1 and F2 items, which represent a teachers’ strength, is the following: F1_30111 STS Interaction, F1_40161 Social Responsibility contamination, F1_20141 Government politics a country, F1_10111 Science F2_10421 Interdependence Quality of life, F2_50111 Union two cultures, and F2_60521 Gender equity.

Some items reach negative scores in both forms (F1 and F2), though their mean indices do not attain low enough scores to be considered symmetrical to the positive ones. Nonetheless, the items with negative indices, which represent a teachers’ weakness, are the following: F1_20411 Ethics, F2_40421 Application to daily life, F2_90111 Observations.

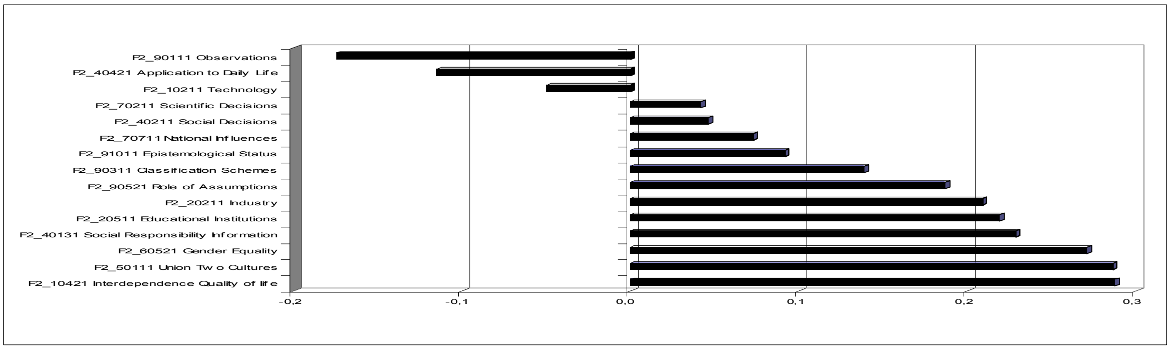

Figure 2. Average item indices for the 15 questions of the Form 2.

Similarly, the categorical and the sentence variables with highest positive and lowest negative indices could be used to identify the specific strengths and weaknesses. Each of the hundred sentences represents a specific conception on NoS, and the whole set conform the teacher’s thinking; approximately, two third of them do not attain a satisfactory level to be deemed quality conceptions for a fair science teacher. The number of these variables that are high and low is still greater than previous ones to be displayed here in the affordable space of this paper. The following example displays the classification of the sentences in an item as weakness, strengths, or medium, according to their mean index scores.

Table 2. Text of an item (10421) that displays the classification of its sentences as weaknesses (italic), strengths (bold), and medium, according to their mean index scores.

10421 In order to improve the quality of living in our country, it would be better to spend money on technological research RATHER THAN scientific research.

A. Invest in technological research because it will improve production, economic growth, and unemployment. These are far more important than anything that scientific research has to offer.

Invest in both:

B. because there is really no difference between science and technology.

C. because scientific knowledge is needed to make technological advances.

D. because they interact and complement each other equally. Technology gives as much to science as science gives to technology.

E. because each in its own way brings advantages to society. For example, science brings medical and environmental advances, while technology brings improved conveniences and efficiency.

F. Invest in scientific research – that is, medical or environmental research – because these are more important than making better appliances, computers, or other products of technological research.

G. Invest in scientific research because it improves the quality of life (for example, medical cures, answers to pollution, and increased knowledge). Technological research, on the other hand, has worsened the quality of life (for example, atomic bombs, pollution, automation, etc.).

H. Invest in neither. The quality of living will not improve with advances in science and technology, but will improve with investments in other sectors of society (for example, social welfare, education, job creation programs, the fine arts, foreign aid, etc.).

The previous table evidences some common features for all items: on each issue (item), the teachers hold at the same time strengths and weaknesses. Some sentences exhibit appropriate conceptions (A, D, G, H), while the remaining sentences feature uninformed conceptions, either a clear weakness (C) or a conceptions that not attain a sufficient high level to meet the teachers needs for a quality teaching of NoS (B, E, F).

Differences between pre-service and in-service teachers

The methodology allows the application of inferential statistics in hypothesis testing, in particular, the simplest form of testing refers to group comparison, which is applied here to compare NoS conceptions of pre-service and in-service teachers. To find out the variables that might display significant differences between groups, a two-way between-groups analysis of variance was conducted to explore the impact of teaching practice on teachers' NoS understanding, as measured by the three hundred variables of questions, categories and sentences (dependent variables).

Overall, few variables (19 for the form 1, and 24 for the form 2 of the total 300 variables involved in the two forms) displayed a statistically significant main effect ($p < .01$; $d > .30$) between in-service and pre-service teachers. However, the differences do not display the same sign, as some differences are positive (in-service teachers score higher than pre-service teachers), and other are negatives (in-service teachers score lower than pre-service teachers). Thus, not only the relevant differences are comparatively scarce, but also they do not display the same trend for all the significant variables favouring one group over the other.

Summing up, these results do not support the hypothesis that the practice of science teaching improves teachers NoS conceptions. This is evidence that improving NoS understanding requires explicit teaching of NoS contents, and implicit practices such as teaching science are not enough to improve teachers' conceptions.

CONCLUSIONS AND IMPLICATIONS

The new instrument and methodology improves the validity and reliability of the previous instruments and avoids the usual objections, such as forced answer (election of just one sentence). Moreover, they contribute to identify qualitative features, such as strengthens and weaknesses of NoS understanding, and to normalize the scores and analyses, which allows standardized application of the hypothesis testing statistics, such as comparisons among groups. On the other hand, the methodology allows quick and easy assessments for big representative samples, which overcomes the limitations to case studies or small samples, to identify the teachers' strongest beliefs (those that highly fit the experts' current knowledge), and the teachers' weakest beliefs (those that oppose the experts' knowledge).

The assessment instrument and method fit the requirements suggested by Allchin (2011) for appropriately assessing functional NoS understanding: authentic context, well-informed analysis, adaptability to diagnostic, formative or summative evaluation, adaptability to single, mass, local or large-scale comparative use and the respect for relevant stakeholders; further, the research project PIEARCTS is an example of large-scale applications across seven countries and involving over 16,000 valid answers (Bennássar-Roig, Vázquez-Alonso, Manassero-Mas, García-Carmona, 2010; Manassero et al., 2010).

The results provide a picture of teachers' NoS conceptions more complex than usual (Lederman, 2007): the teachers' poor conceptions coexist with the appropriate ones across all the NoS topics. Many teachers' NoS conceptions (about two third of explored conceptions) do not achieve the high level required to quality teaching of NoS. The appropriate beliefs could be educationally worth, because they can be used as pedagogical hooks in teacher training and the planning of teaching NoS curriculum.

It is usually agreed that years of teaching improves the teachers' pedagogical content knowledge, so that in-service teachers would have displayed higher scores than pre-service teachers (Abd-El-Khalick & Lederman, 2000; Lederman, 2007). In spite of this somewhat optimistic trait, the comparisons between pre-service and in-service teachers display scarce relevant differences: the differences in favour of pre-service teachers balance those in favour of in-service teachers, and both groups seem more similar than different. As Spanish teachers have not been taught on NoS (control variable), this study evidences that science teaching practice by itself does not contribute to refine the teachers' NoS conceptions. Thus, it would not be expected that teaching experience could (implicitly) train teachers on NoS. This claim agrees with the current compelling evidence in favour of explicit teaching of NoS.

All in all, the numerous inappropriate, or simply insufficiently appropriate conceptions found in the science teachers' thinking, together with the lack of effectiveness of teaching experience to improve this situation, put forward the necessity of designing and implementing training programs that involve teachers in an explicit and reflexive analysis of NoS topics for both pre- and in-service teacher education (Hanuscin, Akerson & Phillipson-Mower, 2006). The aim ought not to be teacherz become philosophers of science, or better knowledgeable on NoS, but more competent teachers to teach effectively NoS issues within science classroom.

DEVELOPING CHILDREN'S VIEWS OF THE NATURE OF SCIENCE THROUGH ROLE PLAY

Cakici, YILMAZ and BAYIR, Eylem
Trakya University, Turkey

Abstract: In this study, we aimed to investigate the effect of using role play (portraying a scientist‟s life story) on the children‟s views of the nature of science (NOS). The study was carried out at the Children‟s University of Trakya in Turkey in 2010. The research sample consisted of 18 children, aged 10 to 11. Children met for ten days for approximately three hours per day. They completed the pre- and post-tests including 16 open-ended questions in order to reveal changes in their views of the NOS before and after the role play activities. The findings revealed that the children had more informed views of the target NOS aspects in comparison to their views prior to the role play activities. A large majority of the children (around 80-85 percent) started out with naive conceptions of the target NOS aspects. Following the role play activities portraying scientists‟ lives, there was a 40-45 percent positive change in children‟s views of the tentative, empirical and creative/imaginative aspect of the NOS. The most substantial change occurred in their views concerning scientific method, with a shift of 72 percent. These results indicate that role play oriented activities portraying scientist‟s life stories could be used as one of the exciting and constructive ways of developing children‟s understanding of the NOS.

Keywords: Nature of science, role play, drama, primary science.

INTODUCTION

In the last two decades, the nature of science, as an essential component of scientific literacy, has become a slogan in science education all over the world. Many reform documents in science education (AAAS, 1993; NRC, 1996) emphasized the crucial role of enhancing students‟ informed views of aspects of the NOS. AAAS (1993) and NRC (1996) underlined that scientific fact/knowledge oriented science teaching focusing narrowly on the laws, concepts, and theories of science does not lead to an understanding of how science itself works. In order to overcome this deficiency, the strong focus for pupils in the early grades, should be on gaining experience with natural and social phenomena, and on enjoying science. Compared to traditional methods of science teaching, use of role play/drama to portray the lives of scientists may provide students with "a more authentic sense of science", especially regarding how science works (Boujaoude et al., 2005, p.259). Odegaard (2003), in her extensive review of the literature on drama activities in science education, emphasized that the use of drama in a well-considered manner with the guidance of reflective science teachers may offer creative and non-authoritarian learning environments for students. Through stories of science and the experience of enacting scientists‟ lives, students may gain better insight into the nature of scientific practice. According to Yoon (2006), two characteristics of science drama are worth of emphasis; 'story' and 'liveliness' of its performance. While events and characters in the „story‟ enable individual emotional participation and empathetic learning, the „liveliness‟ of science drama allows students to express and adapt their ideas in a learning environment which is quite non-authoritative.

Despite the successful performance of 'The Blegdamsvej Faust' drama in 1932 by Bohr's students, there is still a dearth of studies on role play/drama in science education. However, the few studies reported in the literature found that role play/drama has a positive effect on children‟s science learning. Bailey and Watson (1998) investigated the advantages of utilizing drama/role play in developing understanding of basic ecological concepts with students aged 7 to 11. They reported that a structured role play activity, the Eco game, as an active learning strategy appeared to have an important part to play in the generation of concepts relating to ecology. Boujaoude et al. (2005) explored the effect on conceptions of the NOS of using drama as a supporting learning strategy with older students from grade 10 and 11. At the end of the study, it was found that the students who participated in the drama activities possessed more informed the NOS views than the control group.

RATIONALE

In this study, we aim to investigate the effect of using role play activity portraying a scientist‟s life story on upper primary level children‟s views of the NOS. We focus on the tentative, empirical, denial of a prescribed scientific method and on the creative/imaginative NOS. By critically investigating scientists‟ lives and work methods and by role playing, students might become aware that scientists fail as much as they accomplish (Boujaoude et al., 2005, p.259), that they do not follow a universally accepted a scientific method, that science does not provide absolute proof, and finally students may substitute their naive NOS views with informed ones.

METHODS

The study was carried out at the Children‟s University of Trakya in the Northwest part of Turkey and was organized during the summer of 2010. The participants consisted of 18 children, aged 10 to 11. The study lasted two weeks (ten week days) and approximately three hours per day including breaks. The pre- and post-tests including 16 open-ended questions were used.

In this study, the life story of two scientists (Isaac Newton and Marie Curie) was selected for the role play activities to be performed by the children. The authors initially prepared a power point presentation about the lives of those scientists. Both researchers simultaneously supervised the participants during the role play activities. On the first day, after a brief introduction, the pre- test was given to the children. Then, in order to attract the children‟s attention to the lives of the scientists, the researchers directed various questions concerning the scientists. During this activity, students were all given the opportunity to express their ideas freely about the scientists and scientific process. This was followed with the presentation of the lives of two scientists.

On the second day, the children were divided into three groups of 6. While one group of children performed the role play, the others participated as the audience but the groups all had a chance to role play at least once. Performers initially were selected as volunteer among the children. Then, the researchers introduced a detailed step by step description of the life of Newton. At intervals during the presentation, the researchers portrayed the roles which children would be invited to play, and encouraged the children to focus on, talk and improvise about critical incidences in the scientist‟s life. Later, the authors, together with children‟s help, prepared the classroom so that the children could characterize some crucial instances in Newton‟s life. On the third day, the children performed the role play. The children were reminded by the authors what role they would play and given a brief outline of the situation to be portrayed. At each stage, children were encouraged to improvise within the situation to be portrayed.

On the fourth day, the children were experienced in role play, and thus performed their roles more successfully in a relaxed and pleasant atmosphere. Some students were really very eager to repeat the role play. Hence authors required the children to take turn in different roles as they performed with their classmates. During the role play activity, we explicitly asked a number of critical/taught provoking questions in order to touch aspects of NOS. "What do you think of how Newton showed the existence of gravity?" "Where is the gravity in this class?" In this way, children had an opportunity to think about the NOS. Fifth day started out with a small ice-cream party, aiming to encourage children to chat more enthusiastically and answer questions about the NOS e.g. "Do you think that Newton and previous scientists think same thing? Why?" The following week, a similar strategy was adopted illustrating the life of Marie Curie.

RESULTS

Student responses were categorized as naive and informed. Naive category represented inadequate responses with regard to the target NOS aspect. For example, some students stated that scientific knowledge was subject to change over time but attributed that change solely to the development of new technologies or the accumulation of new data. Informed category included responses referring reinterpretation of existing data from a different perspective. Student responses were initially categorised independently by two of the researchers. The researchers sorted out differences by reviewing the responses. Here, we report the children‟s responses to four questions in the pre and post-test. The question "Do you think that all scientific knowledge in your science books can *change* over time? Please, explain your reason" assessed students‟ understanding of the tentative NOS. Although only 3 children (17%) in the pre-test provided informed views about the tentativeness of science, this increased to 11 (61%) after role play activity. While one child in the pre-test determined change to be solely due to technological developments, in the post-test she stated that "different scientists may think differently and produce new things like atom models. Newton‟s ideas were different from the previous scientist." The question targeted the empirical nature of science asked children "For you, how science is different from the other subjects you are studying?" While 39 percent of the children gave relatively informed statements, this increased to 78 percent in the post-test. The following is a child‟s statements in the pre and post-test respectively: "Science explains to us everything in the world. Through the experiments, science provides absolute knowledge." "Science saves us from wrong knowledge. For science, investigating nature and space, and making experiments are very important."

The question about multiple methods of investigation revealed the most substantial shift in the views of children. Although none of the children initially held informed views of scientific method, following engagement with the role play activities informed views rose to 72 percent. For example, a child initially stated that "scientific method is very important. To be successful and practical, a scientist should simply follow scientific method and pursue the way of doing science as the previous scientist". However, after the role play, the same child stated that "I think deep thinking and questioning about things, like Newton, to be a better way of doing science. We do not need to memorize scientific method." When asked about the role of human creativity and imagination in science, informed views increased from 22 percent to 67 percent after role play. One child expressed that "Without imagination, scientist cannot put forth big things. Deep thinking and imagination help scientist to find out new things."

CONCLUSIONS AND IMPLICATIONS

Role playing scientists‟ life stories through the guidance of the reflective authors and explicit instruction appeared to have helped children‟s understanding of how science/scientist works, and finally develop a sense of the target NOS aspects. Although a great majority of children (around 80-85%) started out with naive conceptions of the NOS, following the role play activities portraying scientists‟ lives, they tended to develop more informed views of the target NOS aspects. The positive changes were observed for all of the NOS aspects with the most substantial change occurring with the questioning of universally accepted scientific method showing a shift from zero to 72 percent. The shift for the tentative, empirical and creative and imaginative NOS stayed about 40-45 percent. These results support using role play/drama activities to bring about positive changes in students‟ NOS views as previously stated by Boujaoude et al. (2005). It should be noted that in spite of the fact that role play activities improved the children‟s NOS views, just a two week intervention at the children‟s university may not be enough for assimilation and retention the meanings of the NOS aspects.

DISCOURSE AND ARGUMENTATION IN SCIENCE EDUCATION

BUILDING CONTEXT AND CONTINUITY IN CLASSROOM DISCOURSE; A CASE STUDY AT THE HIGH SCHOOL LEVEL

Zeynab Badreddine[1]
[1] UMR ICAR (CNRS, ENS de Lyon, Lyon II University)

Abstract: In this paper, we will present a case study where we focus on the importance of temporal links in teachers' discourse in particular how these links participate in the drawing of classroom content from the beginning of the school year. From a sociocultural perspective and by taking the teaching learning process as a dynamic process, we build our work on three theoretical concepts: (1) the definition of *context and continuity* developed by the works of Mercer (1987, 2008), (2) the definition of macroscopic, *mesoscopic*, and *microscopic* scale taken from the works of physics education for studying the progression of knowledge in time (Tiberghien & al., 2007), (3) and finally the concepts of *themes* and *episodes* in order to organize the taught knowledge respectively at the mesoscopic scale and microscopic one. We will focus in this case study on two episodes situated in a same theme ("the representation of the solar system as an almost empty (lacunar) system"), and extracted from a video-recorded sequence at the beginning of the school year. The teacher in question is an experienced teacher. These two episodes describe how the teacher draws the *knowledge context* and ensure continuity of the class with regard to knowledge on a short scale and on a longer one. It is a study in progress that aims: (1) to understand how different teachers from different disciplines and different profiles manage from the beginning of the school year the construction and managing of knowledge in the classroom discourse, (2) to provide teachers with tools related to the managing of knowledge through time.

Keywords: dynamic approach of classroom interaction, context, continuity, time scale, discourse analysis

Our work is in line with the socio-cultural perspective. This study take into account the studies that highlight the temporal and dynamic dimensions of the progression of taught knowledge in the classroom discourse at a long scale teaching sequence. In this study, we treat classroom interaction as a dynamic process where time is considered as a major parameter in teaching and learning processes. We believe that each action in classroom has its own meaning with regards to the whole context and history shared between the participants (Badreddine, 2009). This dynamic approach is expressed and defined in works such Roth (2010, p. 114), for example, where he assumes that *" the relationship between thought and word is not held constant, which means that a word at the beginning of a lesson or at the beginning of an interview no longer expresses the same thought as it does at the middle of these events or at the end"*. This point of view is shared by works like Mercer (2000, 2008), Lemke (2001), Scott (1998), Mortimer & Scott (2003), Kelly (2007), Roth (2010), Badreddine & Buty (2011).

We consider that the discourse between teacher and students on the one hand and the way that teacher manages this discourse on the other hand, are essential elements for the construction of meaning during a teaching sequence. For Mercer (2000, p. 46), *"using language, we can* *transform the raw material of our shared life experiences into stories which have continuity and coherence"*. In other words, people that share the same space for a relatively long time are able to understand each other by referring to a past shared instant and to construct the future by referring to these shared moments. They construct a space where every element developed its own meaning with regard to the participants. In addition, Mercer (2008, p. 35) underlines that language is a *"prime tool for making collective sense of experience, and the extent to which students will perceive cohesion and coherence in their classroom work may be heavily dependent on how dialogue mediates that activity"*.

In this perspective, we will present a case study where we focus on the importance of temporal links in teachers' discourse, in particular, how these links participate in the drawing of classroom content from the beginning of the school year.

This work is a part of a European project. As part of this project, we have taken data in 4 different French schools in Physics, Math, and Biology lessons that evolve seven experienced teachers. This study aims to compare regularity and variability between the practices of teachers of a same discipline and of different ones. Our aim is to describe how teacher ensures the evolution of knowledge and of the class organization. We assume that these two dimensions are strongly linked and that students' access to knowledge depends on their management. We will focus in this paper on the first level: the evolution of knowledge in a class discourse.

THEORETICAL FRAMEWORK

We build our work essentially on three theoretical concepts:

(1) The definition of context and continuity developed by Eduards & Mercer (1987). Mercer defines continuity by referring to the context. From Mercer's point of view, context "refers to everything that the participants in a conversation know and understand, over and above that which is explicit in what they say, that contributes to how they make sense of what is said". Thus, *"continuity is the development of such contexts through time"* (Eduards & Mercer, 1987; p. 63). The term *continuity* refers to and puts a stress on the evolutionary construction of meanings through discourse interaction, establishing thus coherence between the meanings developed and presented in a past context and the present context (Badreddine & Buty, 2011, p. 778). It involves the idea that the meanings attributed to a taught content in a particular moment evolve during the sequence.

(2) The time scale defined in the work of physics education (Tiberghien & al., 2007) for studying the progression of knowledge in time, its coherence and continuity. These authors define three scales in order to describe and to organize class phenomena through time. In their study, Tiberghien & al. (2007, p.102) define three different time scales for an analysis of phenomena related to the teaching and learning process: *"the macroscopic scale that corresponds to the academic time (weeks and months), the mesoscopic scale that corresponds to the didactic time (minutes and hours), and finally the microscopic scale that represents a smaller granularity, around minutes and seconds. This microscopic scale is at the level of utterances and gestures of actors [...], the level of interactions"*.

(3) Finally, in order to organize the taught knowledge respectively at the mesoscopic scale and microscopic one, we borrow the concept of "theme" (idem) and "episodes" (Mortimer & al, 2007). A theme is defined as the *"central topic of a discussion during a given time interval in the classroom. These units have a structure, with boundaries and a thematic coherence. They include* *most of the time an introduction and a conclusion, the majority of utterances is connected to the same theme"* (Tiberghien & al., 2007, p. 97, our translation). A theme represents the central topic of the discussion during a given time interval in the classroom. *"The thematic units (Tberghien & al, 2007) [are used] in order to structure the taught knowledge at the meso-scale (time scale of a few dozen of minutes) by its content"*. As for the notion of episode, it represents *"a coherent set of actions and meanings produced by the participants in interaction"* (Mortimer & al., 2007, p. 61–62). The episodes provide access to the rhythm of the classroom life, the dynamics of the classroom interaction and progression of taught content, at the microscopic level.

Consequently, we are interested to underline how teacher assures the construction of a shared content during time from the beginning of the school year. We will be placed in this work at the level of the three scales defined above by presenting two examples on how a teacher, with his students, in a particular theme (mesocopic scale), relates the microscopic scale of taught knowledge with the macroscopic one by referring to a same-shared context.

CONTEXT AND DATA COLLECTION

The two cases that we will refer to in this paper are extracted from the fifth session (Figure 1) of a tenth grade class (high school level) where the teacher works with the student on elementary notions on the solar system. We are at the beginning of the year (Figure 1) where students and teacher are in a stage of getting to know each other. The teacher of this class is an experienced teacher and is engaged in a group of research and development of teaching sequences in physics and chemistry education. We have video-recorded, continuously during three months, the teacher in his moves and his interaction with his class along thirteen sessions. The recording of the entire sequence was a way to preserve the meaning of actions through time and their continuity over sessions.

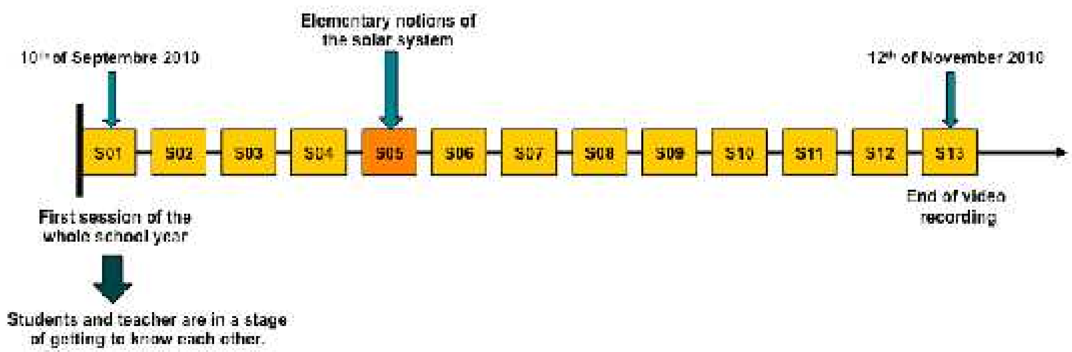

Figure 1. Sessions recorded from the beginning of the school year

METHOD OF ANALYSIS

Consequently to our theoretical positioning, our method of analysis consists in visualizing the sequence throughout its chronological progression in order to maintain how the context is co-developed in time between teacher and his students in interaction. We have broken down the session into themes at the mesoscopic scale and we have analyzed the discourse at the microscopic one by cutting each theme into episodes (Figure 2). The microscopic scale of an episode is the result of its adaptation with our assumptions: to see the construction of taught content during time, we have to be placed at the microscopic level (order of interactions and utterances) in order to study how knowledge is emerging in classroom discourse.

Putting in relation these two scales enables us to understand, from the one hand, how the knowledge emerges and how it is constructed and linked through the microscopic level (episodes), and from the other, to organize this content at the mesoscopic scale using themes.

For this study, we have selected episodes (Author's reference) that underline the temporal links that the teacher makes in his discourse. The division into episodes covers the entire sessions (Figure 2).

We have implemented our method of analysis on Transana®, a tool for transcriptions and analysis of qualitative data, in order to manage our set of data.

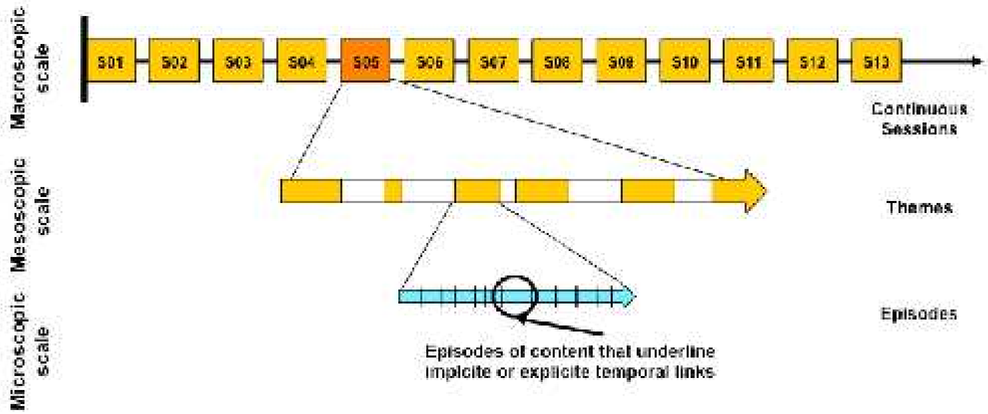

Figure 2. This figure represents the three scales that organized our study: the macroscopic scale at the first row, the mesoscopic scale at the second row and the microscopic scale at the final row.

RESULTS AND DISCUSSION

The two episodes that we will describe in this paragraph are localized in the theme "the representation of the solar system as an almost empty (lacunar) system" (Figure 3).

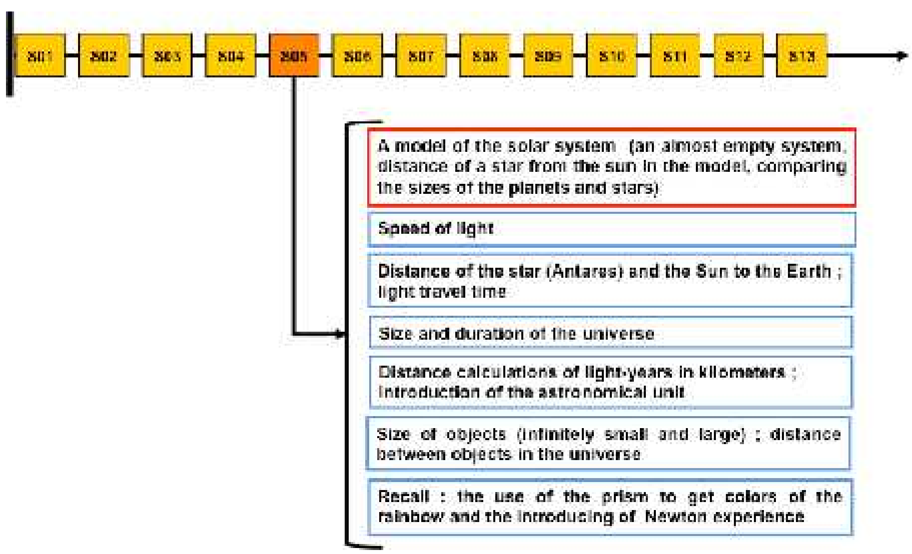

Figure 3. This figure represents the themes progression in the 5th session. The episodes, in which we are interested, are localized at the first theme of this session (red frame)

Long term continuity

The first episode (transcription below) is located at the conclusion of the activity "the model of the solar system, an illustration of an almost empty structure". In this episode the teacher indicates to the students the presence of another almost empty system other than the solar system and asks them if they know it. He then underlines and *announces*[1] that it "will be soon visited" (transcription 1, turn 3, underlined text).

1 Teacher: […] what does it mean that the solar system is lacunar (almost empty) […]/ there is fundamentally vacuum that's what we call lacunar (almost empty) ok (turns on the blackboard and writes) Solar System / The solar system we'll say is lacunar (almost empty) because it is fundamentally

2 Student: composed of

3 Teacher: […] is essentially lacunar (almost empty) because it's occupied by vacuum (end of writing), […] and there will be another system other types of system that will be very lacunar <u>as we will soon explore</u> / in your opinion what type of system

4 Student: the black hole

5 Teacher: […] oh no black hole is exactly the reverse / a black hole is the maximum density of matter we'll find nothing but matter it is exactly the opposite/ raise your hands so I'll give you

6 Student: atoms

7 Teacher: atoms

8 Student: molecules

9 Teacher: atoms and molecules/ an atom is mainly occupied by vacuum because there will be a small nucleus in the middle and the electrons around/ but there will be plenty of space at the atom scale between the nucleus and electrons ok so in fact even you / I think I've already said it

10 Student: we are constituted

11 Teacher: you are essentially made up in volume of vacuum

Transcription 1

In this episode, the teacher draws what we call a *long term continuity* where he prepares the students to the coming of a similar system later on in the sequence, "the atoms and the molecules" systems, as the students guess during the interaction with the teacher (turn 6 and 8). Students do not know when this topic will take place.

In this episode, the teacher puts an *anchor point* with the future by establishing a continuity of a taught content in physics with a chemistry content that will be introduced later on. The teacher gives information on the characteristic of the atom in advance. In addition, the teacher includes the students in a discussion built on future elements of the lesson ("in your opinion what type of

---

[1] Categories of knowledge articulation defined in Badreddine & Buty (2011, p.784) : to announce, to call, to postpone, to resume, to advance, to remind.

system", turn 3), by having them name the other almost empty system (turn 6 and 8). We assume that this action has increased the bind of both students and content taught with the future.

Short term continuity

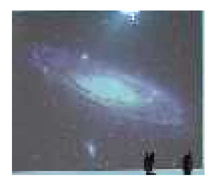
As for the second episode, it is located at the transition between the theme "a model of the solar system" and the theme " the speed of light" (figure 3). This episode takes place while the teacher project on the board a short film, which shows the differences between the sizes of planets situated in and outer the solar system. At the end of the film, while its last picture which represents the universe and the stars is displayed on the board, the teacher asks the students to "watch the diversity of colors" of the stars in the universe (transcription 2, bold text, picture):

Teacher Well it was another way of presenting things/ **watch the stars it will** <u>make a transition with the following</u>**/ watch the diversity of colors ok in the universe** the diversity of colors of the stars ok […]

Transcription 2

In this episode, the teacher makes an implicit reference to the theme of "the light spectrum and the phenomena of light scattering" presented in the session 4. This reference is done by transposing the context of an episode in the previous session (transcription 3, bold text and picture) to this session (session 5): "watch the stars […] watch the diversity of colors" (transcription 2, picture and bold text).

Teacher I 'll project a little picture (...) this is a galaxy (...) / **there are plenty of stars** in it/that appear white, but also there are things that appear yellow-orange others appear blue...**so effectively there is a large variety of possible colors** »



Transcription 3

In fact, when the teacher says "watch the stars", emphasizing later "the diversity of colors in the universe" while he refers to the picture on the board (transcription 2), he *calls* a content and a space shared with the students one day before. The teacher projected conscientiously during the session 4 a "little picture of a galaxy" (transcription 3). The similarities of the discourse and of the two pictures in these episodes call one another.

Furthermore, the teacher takes his time to prepare the student to what will happen in the next session (Session 6 and 7) by *announcing* that "it will make the transition with the following" (transcription 2, underlined text).

In this episode, teacher has made what we call a *short-term continuity* with the macroscopic scale between one session before (session 4) and two sessions after (sessions 6 and 7).

CONCLUSIONS AND PERSPECTIVE

This study aims to understand how different teachers from different disciplines and different profiles manage from the beginning of the school year the construction and the progression of knowledge in the classroom discourse.

By these two episodes, extracted from a session at the beginning of the year, we have underlined two examples on how a teacher draws the context of the class with regard to knowledge on a long scale (episode 1) and a shorter one (episode 2). Teacher draws different continuities of his context through time. We can see in these two microscopic episodes (the first lasts in the classroom discourse 45 seconds and the second 25 seconds) indices for a construction of a shared space for a common content.

We assume that by studying the practices of experienced teachers, this work will enable us to underline some of their performs and to bring tools to science teachers related to the managing of knowledge through time, more particularly, tools that enable teachers to explicit to students links between the past, the present, and the future of the taught content. This study is an analysis that will be extended to the other teachers (recorded in the frame of the S-TEAM project) in order to create collections of regularity and variability between teachers' practices. We believe that explicit these links to teachers and pre-service teachers, in order to use them efficiently in there teaching sessions, may increase students learning process. Furthermore, we aim to study the types of knowledge when links are made in the classroom discourse and the position of these links with regard to the progression of the lesson.

EPISTEMIC FEATURES OF SCIENCE TEACHERS' TALK: COMPARING THE DISCURSIVE PRACTICES OF TWO SCIENCE TEACHERS

Andri Christodoulou[1] *and Jonathan Osborne*[2]
[1] King's College London
[2] Stanford University

Abstract: Contemporary reform efforts within science education emphasise the importance of teaching the content and methods of science, as well as promoting an understanding of the nature of scientific knowledge and the practices of science. One way to promote the epistemic nature of scientific practices in science classrooms is through teaching science using collaborative discourse and argumentation. Argumentation can be seen as a form of epistemic discourse, which can be fundamental to the development of students' epistemological understanding. Yet, little analysis exists of the epistemic discourse initiated by teachers, either in ordinary or argumentation-based instruction in order to model epistemic discourse for the students and prompt them to engage in this form of classroom talk. Therefore, this study, examined the epistemic discourse initiated by two science teachers observed teaching the same groups of Year 9 and Year 10 students throughout a school year, both during ordinary and in argumentation-based instruction. Epistemic discourse was framed based on epistemic operations such as explaining, describing, exemplifying etc. The results suggest that during argument-based instruction the epistemic operations of justification, prompts for justification and prompts for evidence were the most frequent and were dependent on the teachers' views of the nature of argumentation and its use in science education.

Keywords: epistemic discourse, epistemic practices, argumentation, secondary science, case studies

INTRODUCTION

During the last two decades and in light of considerations about scientific literacy and 'science for all' (AAAS, 1989) there has been a major shift in the goals of science education. That is, reform efforts in several countries in Europe, and the United States, now acknowledge the need for students to develop an understanding of issues such as the importance of evidence in the practice of science, the cultural and social influences of scientists, and the strengths and limitations that scientific knowledge possesses, in addition to aims about conceptual understanding and practical work (NRC, 1996, 2011; Millar& Osborne, 1998; Osborne & Dillon, 2008). An in-depth understanding of science means students should not only be aware of 'what we know' but also of 'how we know what we know and why we choose to believe it over alternatives' (Duschl, 2008, p.163). Thus, science educators need to address the epistemic practices that characterise the scientific endeavour. Kelly (2008) defines epistemic practices as 'the specific ways members of a community propose, justify, evaluate, and legitimise knowledge claims within a disciplinary framework' (p.99). This study argues that one way to foreground the epistemic practices of science within science education is to view the teaching of science as argument.

Argumentation is an integral practice of science which explores the construction and critique of scientific knowledge fostering not only the critical scepticism that is the hallmark of the scientist but also enhancing student conceptual understanding (Kuhn, 1993, Osborne, 2010). During argumentation-based instruction, students use evidence to support their claims and evaluate other individuals' claims and, in this manner, are enculturated into the discursive practices of scientists (Erduran & Jiménez-Alexaindre, 2008). Consequently, argumentation constitutes a form of epistemic discourse (Sandoval & Morrison, 2003); a way of talking that can help students develop a more informed view of the nature of science and its epistemic practices. Epistemic discourse could include instances of asking for evidence to support and justify a claim; making students consider opposing views and critically evaluate which one is better and why; explicit mention of the nature of evidence that students need to be using in their explanations and of the role of this evidence for their arguments; and providing or creating counter-arguments. The function of epistemic discourse is to help students acquire scientific knowledge whilst at the same time, engage students to the discursive and reasoning process necessary for that knowledge to be acquired.

Sandoval and Morrison (2003) argue that simply participating in activities where students need to construct their own explanations and provide evidence to support these explanations does not necessarily provide the means for students to develop an informed epistemological understanding. In their research, the students on which they focused had the opportunity to engage in such activities but at the end of the study, they did not demonstrate any substantial improvement to their understanding of the nature and role of scientific theories and evidence. Sandoval and Morrison (2003) add that students, in addition to engaging in such activities, need to be provided with opportunities to discuss the reasons and criteria they use for choosing one explanation over another, as well as to discuss the role of evidence for their explanations. As a consequence, 'to develop students' epistemological ideas, the nature of the discourse surrounding students' inquiry may be more important than the inquiry itself' (p.383). Ohlsson (1996) suggests that through an examination of the discursive actions of teachers and students, several epistemic operations can be identified, which promote higher-order thinking and understanding since 'collections of facts do not in and of themselves constitute understanding' (Ohlsson, 1996, p.48). These operations are Describing, Defining, Predicting, Exemplifying, Explaining, Critiquing (Arguing) and Evaluating. However, a careful examination of Ohlsson's list of epistemic actions shows that it is not exhaustive, as he suggests, since there could be other discursive epistemic operations carried out in classrooms, and especially the science classroom, such as compare and contrast, classifying, calculating and appealing to analogies and metaphors (Collins & Ferguson, 1993; Jiménez-Aleixandre et al., 2008; Mason, 1996). Utilising the notion of epistemic operations to analyse classroom talk during argumentation instruction is a way to identify the discursive actions of the teachers and find ways to help them model and further develop the use of epistemic discourse with their students.

RATIONALE

Research to date would suggest that there has been little analysis of the epistemic discourse initiated by teachers, either in ordinary or argumentation-based instruction. While there have been many studies of argumentation in the context of science education, many of these have focussed on student-student discourse and not on the nature of the discourse initiated by the teacher. As a result, this study aims to fill this gap in the literature. Specifically, the question of interest for this study, part of a professional development project aiming to help teachers incorporate argumentation into their everyday practices, was whether the use of argumentation-based activities enhanced the use of epistemic discourse in the science classroom when compared to 'ordinary' science lessons of two secondary science teachers.

CONTEXT OF THE STUDY

This study was conducted as part of a funded two-year Professional Development project (PD project hereafter) which aimed to help science teachers and their departments in four different schools to incorporate argumentation into their everyday practices. Argumentation was framed for the teachers based on Toulmin's (1958) framework of an argument, which consists of a claim; warrants or evidence; backings, rebuttals and qualifiers. Within each intervention school, two teachers acted as lead teachers for their departments. The lead teachers attended five workshop days during which they were introduced to the practice of argumentation, helped develop their knowledge of implementing argumentation in their science classrooms and at different age groups, and worked towards a dialogic perspective of science instruction. Subsequently, these eight teachers acted as lead teachers for their departments organising departmental reflective meetings and providing support to the science teachers of their own departments, which attempted to use argumentation activities in their science lessons.

METHODS AND ANALYSIS

This study utilised a qualitative case study design to create a detailed account of two teachers using argumentation and their students. The nature of the case studies developed were 'exploratory' emphasising the investigation of an event with the intent to create further hypotheses for future investigation (Yin, 2009). Two science teachers, from two secondary schools in London, one with a Year 9 class (13-14 years old) and one with a Year 10 class (14-15 years old), were followed throughout a school year. As a result, 13 lessons (6 argument-based) and 12 (4 argument-based) lessons respectively of the two teachers were observed in their classrooms. Lessons were video-recorded to capture the verbal interactions between teacher and students. The lessons observed focused on argumentation in different ways, varying in time, number of activities and topic investigated depending on the teacher's objectives and planning. Other data collected include teacher interviews to acquire a fuller picture of their conceptions about science, its nature and its practices and their beliefs about science teaching, learning and argumentation. In addition informal discussions with teachers about the lessons observed were hold and recorded in field notes.

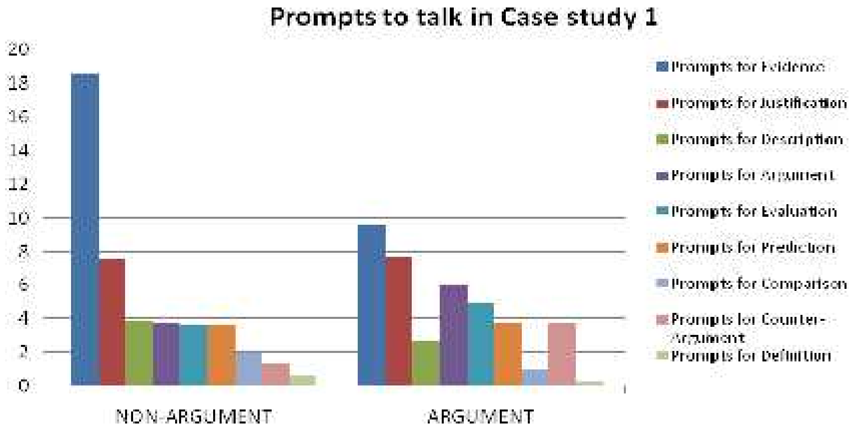
Participant sampling was based on convenience sampling aiming at teachers participating in the PD project, who would be prepared to share more of their time with the researcher and allow for lesson observations for an extensive period of time (one school year). Moreover, criteria such as the willingness to use argumentation even after the end of the PD project, confidence in teaching while observed, demonstration of enthusiasm and commitment to the PD project and an interest in the use of argumentation for teaching and learning science, were utilised to identify the two participating teachers. T1, a male science teacher in his forties with 20 years of science teaching experience at a mixed-comprehensive secondary school located in a quiet, residential area in the north-west of Greater London. T2, was a female teacher in her twenties with 3 years of teaching experience working at a mixed-comprehensive, secondary science specialist school in the north-east of Greater London.

Thematic analysis was used to code the transcripts of the lessons (Boyatzis, 1998) based on a theoretical framework of epistemic operations synthesised from the literature (Jimenez-Aleixandre et al., 2008; Ohlsson, 1996; Pontecorvo & Girardet, 1993). The software for qualitative analysis Nvivo 8 facilitated the coding process of the data. Initially, a reiterative process of open coding was utilised aiming at identifying the main themes coming out of the teachers' responses. The next step of analysis involved the revision and refinement of the themes identified to create overarching categories from the initial themes and use these categories to look for patterns within the case. The epistemic operations identified were framed based on (a) epistemic operations *performed* by the teacher, which were the discursive actions used by the teacher when s/he was attempting to explain, define, describe etc. an event and (b) the epistemic operations the teacher *prompted* students to engage in.

RESULTS

The analysis of the lesson transcripts for the two teachers, indicates that both teachers engaged in the epistemic practice of constructing knowledge claims through epistemic operations such as 'Provides Evidence/Information', 'Description, 'Explanation', 'Argument', Definition' and 'Generalisation'. In the two teachers' argumentation lessons, epistemic operations became more cognitively demanding and challenging as they started prompting students to provide their own arguments or provide justifications from evidence for their opinions/ideas. 'Justification' was utilised by both teachers, although not to the same extent. The justificatory aspect of the practice of argumentation was the strongest epistemic feature of T1's classroom talk, which was also one of the fundamental ways in which he conceptualised the notion of argumentation. Indeed 'the need to justify a viewpoint' was found to be the thematic emphasis in most of his argumentation lessons and the main way in which he distinguished between argumentation and non-argumentation lessons. What is more, T1 utilised 'Justification' and 'Prompts of Justification' as part of his non-argumentation lessons in a way and frequency, which were not substantively different to that of argumentation lessons (Figure 1).

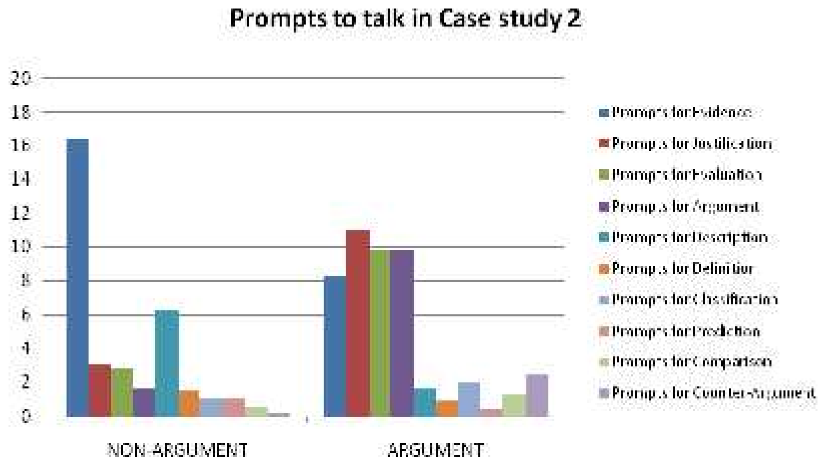
Fig1: The range of prompts in percentages T1 utilised as part of his argument and non-argument lessons



However, T1 did not consider other aspects of epistemic practices such as the need to evaluate knowledge claims and the need to portray to students the processes of evaluation and counter-argument that scientists often engage within their disciplines. As a result, attempts to evaluate claims critically and/or provide counter-arguments were less frequent, even in lessons where the argumentation activities focussed specifically on the evaluation of claims (Lesson 3).

In Case Study 2, T2 utilised 'Justification' and 'Prompts for Justification' consistently in her argumentation lessons, although this was not the case for her non-argumentation lessons, especially her use of 'Prompts for Justification', which was minimal (Figure 2). What is more, it was found that T2's use of justificatory talk was increasing as the year pasted, suggesting that she was still developing her use and understanding of argumentation as an instructional approach.

Fig2: The range of prompts in percentages that T2 utilised as part of her argument and non-argument lessons



Through the two case studies, it was established that the way in which the two teachers utilised epistemic operations and formulated their classroom talk was context-specific. In particular, the epistemic operations found in each teacher's talk depended on the type of lesson they were teaching (argumentation or non-argumentation) and within that, on the particular aspects of argumentation that they wished to address. For instance, Lesson 3 in Case Study 1, (an argumentation lesson) focused on selecting from a number of given statements in order to explain the fall of an object. As a consequence, during this lesson, the epistemic operations used the most were 'Justification' and 'Prompts for Justification' as students had to provide a reason for their selection of statements. Moreover, T2 seemed to use the epistemic operations of 'Prompts for Evaluation' and 'Prompts for Counter-Argument', in the argumentation lessons she taught as end-of-unit lessons (Lesson 1 and Lesson 5), which provided more opportunities for students to evaluate statements and make comparisons. The link identified between the context of the lessons and the epistemic operations that characterised these lessons is valuable in identifying and promoting those contexts that are potentially more likely to advance epistemic aspects of science. For instance, argumentation lessons as end-of-unit lessons could be used to apply and promote the role of the 'critiquer' (Ford, 2008a, 2008b), since evaluative processes seemed to be more evident in these lessons. Nevertheless, ways in which critique and evaluation can become part of everyday science teaching and learning also need to be explored. Students need to see evaluation and critique as an essential element of the process of knowledge generation if they are to grasp the epistemic nature of scientific knowledge and practices.

CONCLUSIONS AND IMPLICATIONS

The results of this study suggest that there is a developmental sequence of epistemic operations from lower-order operations such as description to higher-order operations of critique and evaluation. Thematic analysis of discursive interactions in the field of education has shown how images of science as a body of unequivocal and unquestioned knowledge is conveyed (Lemke, 1990). This study, through focusing on the nature of the teacher discourse and teacher-student interactions looked at whether the use of argumentation-based activities provides a means of transforming the dominance of IRE sequences (Initiation-Response-Evaluation) to one which demands the use of extended and higher-order reasoning by students. Although the data sample is small, the analysis provides an illustration of how the nature of classroom discourse can be transformed from providing declarative knowledge to students and relying on IRE sequences, to a developmental sequence of epistemic operations, starting from construction, moving on to justification and then to evaluation, which may advance epistemic discourse in the science classroom. According to recent recommendations (NRC, 2007) ‘students need support to learn appropriate norms and language for productive participation in the discourses of science’ (p.186) and argumentation can provide this support and assist students participate productively and persuasively in the discourses of science. Students will only begin to view the epistemic practice of science as such if teachers use the full range of discourse acts, or epistemic operations, which support such a practice. As a consequence, future research into ways of developing argumentation practices in science classrooms needs to introduce teachers to the practice of argumentation and at the same time, help them develop ways of structuring their talk in order to promote epistemic discourse.

SCIENCE LEARNINGS AND DEBATES ON PAST BIODIVERSITY IN PRIMARY SCHOOL AND IN HISTORY OF SCIENCE

Patricia Crépin-Obert[1]
[1]CREN EA 2661University of Nantes, IUFM University of Franche-Comté, France

Abstract : The first steps to learn paleontology in primary school and towards the creation of this area of study share similar problemes and obstacles. The choice of words and langage in a primary school discussion between 9-10 years old pupils on an historical controversy proved to be a fruitful moment. Disagreements centered round problem building and artificial objects used as scientific model were the source of confrontation and their interplay can be a double edged sword with problem building being either facilited or inhibited by the object in question. With 9-10 year olds the artificial object triggered a debate, raised questions and built reasoning. However, in the past it proved to be a bone of contention which frozen questioning in the sciences until 17th century in France. Identifying the issue gave rise to new paleontological questions and constructive discussion and criticism on both the heuristic and argumentative levels of the sciences as Voltaire and Guettard proved in the 18th century.

Keywords : In-class science debate, historical controversy, learnings and history of paleontology, epistemological rupture, problem-based learning

CONCEPTUAL FRAMEWORK AND QUESTIONS OF RESEARCH

This study would like to show the importance of controversies for learnings in sciences in order to prove some points of epistemological reference. To prepare the pupils, as future citizens, to develop questioning and argumentation, debat in class-room can be a favourable time. In reference to the construction of scientific knowledge, the historical controversies can be used like a mirror to understand and revisit problems (Popper, 1979) and obstacles (Bachelard, 1938) met by the scientific community. We have conceived a comparative study, didactic and historical, of problems in the field of palaeontology leads to a convergence about relations between problems and obstacles (Crépin-obert, 2010). This study concern the problem of the fossil origin linked to the artificialist obstacle. Two questions lead the research : what reasons are mobilized to explain fossils origin at two communities, classroom and history of sciences ? How the problem is constructed when they debated about a similar epistemic framework, the artificialism ?

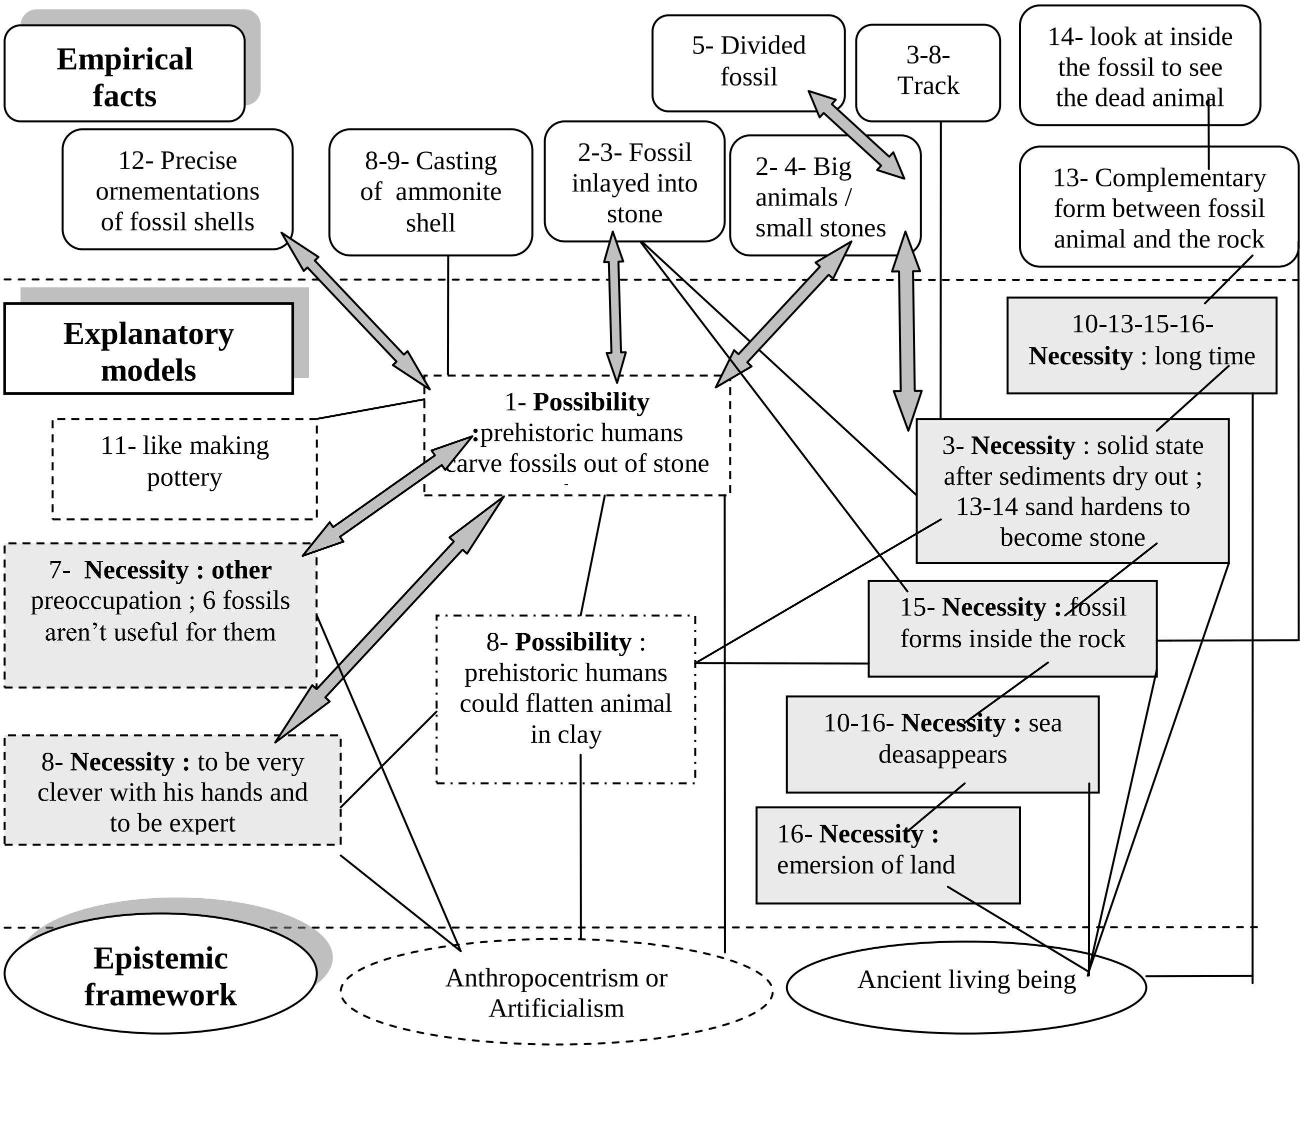
METHOD : A COMPARATIVE STUDY

The collective construction of paleontological knowledge is analysed within the theoretical and methodological framework of questioning coming from a science debates in-class and a historical and original controversy. The heuristic, argumentative and theoritical fonctions of these discussions are compared. Within the theoretical framework of problematization - building a problem- (Fabre and Orange, 1997), a study carried out in a primary school took an interest in transposing the methodology of space of the constraints (Orange, 2002) in the field of palaeontology in order to define the scientific learning objectives. The same tool is used to analyse the controversy in 18th century.

Debate in primary school

During a discussion in science, a co-construction spread between empirical facts in bond with a diversity of fossils and explanatory models. The reasons evoked by the pupils, guided by the teacher are mobilized according to several epistemic frameworks, such as artificialism anthropocentrism, or materialism (schema n°1). The argumentation puts in relation cognitive divergent ideas and scientific methodology. What leads the pupils to raise their questions becoming legitimated (Maulini, 2005), as "Have fossil schells been made by prehistoric humans ?". These various epistemological obstacles were located in history of sciences which bring a retreat necessary for their analysis.

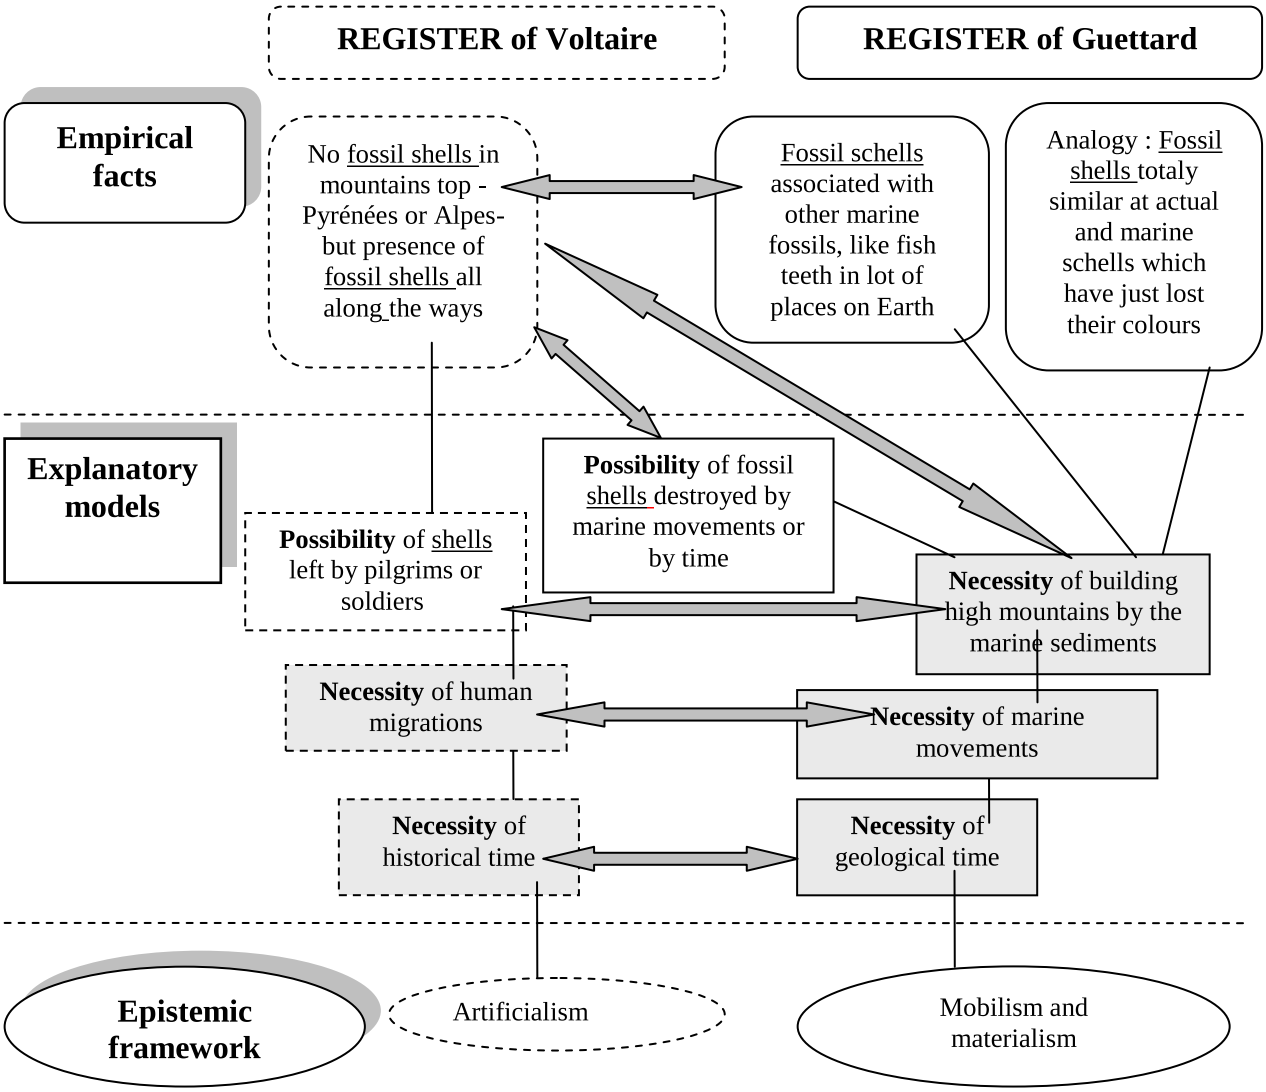
Schema N°1 **: Space of the constraints and the possibilities, an extract of debate in a primary class-room (9-10 years old)**



Historical controversy between two popular well-known people, a scientist and a scholar of 18th century, Guettard and Voltaire.

Voltaire defended the idea of artificialist origin for fossil shells, why not left by pelgrims or soldiers who crossed montains ? Guettard was at odds and defended analogy between fossil shells and actual marine shells. So, the scientific community thaught about necessary marine origin and so necessary marine movements a long time ago.

Schema N°2 : **Space of the constraints and the possibilities about fossil shells and Earth formation:** "When Guettard answers Voltaire fossil shells"



DISCUSSION ABOUT THE COMPARATIVE STUDY

We can end up in several levels of constructions of problems in didactic and in history of science ; furthermore we can notice different relations between problem and obstacle (Peterfalvi, 2006). More, we can separate process of paleontological knowledge, marked by the possibilities and the requirements mobilized by two communities under discussion. Firstly, even the results appear similar with common problem and obstacle, the process are different in the two discussions. The tension between two registers, empirical and explanatory, is especially interesting to compare. The pupils come in questioning and try to find several explanations based especially on possibilities and implicit necessities. In fascinating charges the initial problem thus, problematization requires three specific learnings : how to learn to distance empirical register from explicative register, how to learn to argue and how to learn to question the scientific objects and models. Where as, in the historical discussion, the two opponents built explicit necessities or impossibilities. Moreover, the points of view of protagonists mobilized differently two scientific registers. Over this hypothesis of pilgrims, laughed at by Buffon then by Guettard, Voltaire proposed, in fact, four others hypothesis on origin of fossil shells (Carozzi, 1983). He built his research on heuristic argumentation mainly to fight against the idea of Deluge. While Guettard only retained biological and geological facts and was afraid to propose some theorical ideas.

The pupils, the teachers and the great public keep a fascination for current subject like human fossils and their age or their relationships, fossil dinosaurs and their causes of disappearance or their relations with living birds, in general the origin and the extinction of species (Rudwick, 1985; Gould, 1989). The analyse of past controversies around fossil shells allows to understand these nowadays controversies about past or current biodiversity. Generally, it allows to define the nature of the scientific knowledge, that is to say : explanatory, debated, temporary and always may be refutable (Popper, 1979). The history of the living beings, accepted today, will allow a lot of new developments. Impossibility, possibility and necessity are epistemolgical references to construct scientific knowledge, better than mistake and truth. They could be an alternative method to define the scientific learning objectives which can favour scientific teaching : to distance empirical register from explicative register, to argue and to question the scientific objects and models.

THE CASE OF DESIGNING AND VALIDATING A TOOL TO ASSESS 11-14 YEAR OLD STUDENTS WRITTEN ARGUMENTATION

Maria Evagorou[1], *Elena Papanastasiou*[1] *& Jonathan Osborne*[2]
[1]University of Nicosia, Cyprus
[1]Stanford University, USA

Abstract: The purpose of this paper is to present the process of designing and validating a tool to assess 11-14 year old students written argumentation in science. Given the emphasis in argumentation in science education in the recent years, methodologically the assessment of argumentation has become one of the dominant issues in the field. In this paper we present two written argumentation tools that were designed for 11-14 year old students, the validation process, and the main outcomes from testing the argumentation tools with 246 students in the UK. The analysis of the data from two versions of the questionnaire (Test A and Test B) show that both tests are reliable for evaluating written argumentation when the first item is removed (Cronbach's alpha .674 for Test A and .705 for Test B). Additionally the analysis of the data implies that choosing a convincing argument is more difficult for the students than any of the other three aspects of argumentation that were evaluated in these tests (choosing a convincing counterargument, writing an argument, writing a counter-argument). Finally, the results from the questionnaire suggest that argumentation might be content specific. Implications for research include the design of a new tool combining the questions from both tests, using aspects of the questionnaire to explore whether argumentation is context specific, and exploring whether deciding on a convincing argument is a higher sub-skill compared to writing an argument.

Keywords: argumentation, evaluation, written assessment, reliability, science

INTRODUCTION

Argumentation has been a prominent field in the science education community for the past years (Jiménez-Aleixandre & Erduran, 2008) and recent reports in the field identify the need for a science education that places an emphasis on understanding argumentation and explanation as part of the practice of science (Duschl, Schweingruber, & Shouse, 2007). Students' arguments have been analyzed using a variety of methods and data sets – researchers have analyzed interviews in which people engaged in argumentation, videos of people constructing arguments, students' artifacts created during the instruction, and written essays (e.g. Jimenez-Aleixandre, Rodriguez, & Duschl, 2000; Erduran, Simon & Osborne 2004; Sampson & Clark, 2008). However, according to published research no single valid instrument exists to evaluate young students written argumentation skills, a tool that can potentially be used as a measure of whether students improve or not their argumentation during the instruction. Hence, the main purpose of this study was to design and evaluate a questionnaire to assess students' arguments through a combination of open-ended and Likert scale questions. Therefore, the research questions explored in this paper are:

(a) Is the current assessment tool an appropriate tool for measuring students' argumentation skills*?*
(b) What can we say about students' written argumentation skills based on this test?

RATIONALE/IMPORTANCE

As stated above, argumentation has been the emphasis of many studies in recent years, however we do not have valid tools to help us evaluate students' written argumentation and enable us as researchers to follow the progress of students, and measure the impact of research programs. Consequently, teachers do not have a consistent way to measure their students' performance in argumentation. Hence this study is important since it seeks to explore this relatively new area, and additionally help us understand whether such a tool is appropriate for the evaluation of argumentation. The theoretical framework underlying the design of theassessment test was that of Toulmin's (1958) view of the elements of an argument. According to Toulmin's framework the essential elements of an argument are claims, data, warrants and backings. Counter-arguments are also important, especially in a dialogue, since one of the reasons that students should develop their argumentation skills is to enable them to evaluate claims and data and decide, in their everyday life, whether an argument is valid or not (Millar & Osborne, 1998).

METHODS

In order to test whether the current assessment tool is an appropriate tool for measuring students' argumentation skills a mixed-methods approach was used. The initial pilot testing of the questionnaire was based on open-coding, whilst the validation of the questionnaire was based on a statistical analysis of the responses provided. Several versions of the assessment tool were designed and pilot tested before finalizing the two versions presented in this proposal (Test A and Test B). Each test includes four items, each one designed to test an aspect argumentation as shown in Table 1 below. The choice of these four parts is based on the structure of argumentation, and the fact that argumentation is seen as a means of understanding knowledge and advancing new knowledge (e.g. Driver, Newton & Osborne, 2000). Hence the decision to ask students to choose the most convincing arguments and counter-arguments and then construct their own arguments and counter-arguments lies in the fact that both are part of the argumentation framework that informs the design of this study (Toulmin, 1958). Table 1 below provides an overview of the parts of the two questionnaires, and the context for each of the questions.

Table 1: Overview of structure and content of the two questionnaires

	Choosing a convincing argument	**Choosing a convincing counter-argument**	**Constructing an argument**	**Constructing a counter argument**
Test A	Q1a: Is current used up in a simple electric circuit?	Q2a: Light travels from our eyes to objects?	Q3a: Using chemicals to kill mosquitoes?	Wind energy vs. nuclear factories
Test B	Q1b: Explaining a breath vs. heart rate graph.	Q2b: Weather conditions under which it is possible to snow.	Q3b: Choosing the hardest rock from a list and explaining.	Q4b: Should we use mobile phones at school?

Each one of the four items was evaluated based on argumentation levels. These levels indicate the quality of the argument based on a modified version of the Erduran et al., (2004) framework: Level 4: (most convincing argument) data, warrant, and rebuttal; Level 3: warrant and data; Level 2: warrant only OR data only; Level 1: appeal to authority; Level 0: contradicts the claim or no response.

The questionnaires were administered to a total of 246 students (11-14 years old) in public and private schools in London and suburbs, with 114 students completing Test A and 132 students completing Test B. The decision to design two shorter versions of the tool instead of a longer one was based on observations from the initial piloting of the tool (e.g. the longer version was time consuming). The responses were coded based on the modified version of the Erduran et al. (2004) framework, and then the data were analyzed in SPSS.

RESULTS

Cronbach's alpha, which is a measure of the internal consistency of the items, was calculated for each of the tests. Cronbach's alpha for Test A was .605, and for Test B was .616. The inter-item correlation for both tests (Test A and Test B) which explores if the four items in each test correlate is presented in Tables 2 and 3.

Table 2: Inter-Item Correlation Matrix for Test A

	Q1	Q2	Q3	Q4
Q1	1	0.095	0.187	0.129
Q2	0.095	1	0.459	0.317
Q3	0.187	0.459	1	0.474
Q4	0.129	0.317	0.474	1

Table 3: Inter-Item Correlation Matrix for Test B

	Q1	Q2	Q3	Q4
Q1	1	-0.002	0.14	0.126
Q2	-0.002	1	0.483	0.333
Q3	0.14	0.483	1	0.524
Q4	0.126	0.333	0.524	1

As evident by Cronbach's alpha for both tests, the internal consistency was relatively low in the two tests, with Test B having a slightly higher consistency than Test A. Additionally, the correlation of items in Tables 2 and 3 show than there is a low correlation between Q1 and the other items in both tests. Therefore the scores for Question 1 were removed from both tests and Cronbach's alpha was calculated again as .0674 for Test A and 0.705 for Test B. The internal consistency is relatively high for both tests when the first question is removed from the total scores.

CONCLUSIONS

The analysis of the data from two versions of the questionnaire (Test A and Test B) show that both tests are reliable for evaluating written argumentation when the first item (Question 1) is removed. Additionally, the analysis of the data suggests that argumentation is evaluated best with open ended-questions (Q3 and Q4) since by removing either items Q1 and Q2 from both tests Cronbach's alpha is relatively higher than when removing either items Q3 and Q4 (see Table 4 below).

Table 4: Cronbach's Alpha if Item deleted for both tests

	Cronbach's Alpha if Item Deleted for Test A	Cronbach's Alpha if Item Deleted for Test B
Q1	0.674	0.705
Q2	0.508	0.532
Q3	0.394	0.361
Q4	0.489	0.478

The above implies that choosing a convincing argument is more difficult for the students than any of the other three aspects of argumentation that were evaluated in these tests (choosing a convincing counterargument, writing an argument, writing a counter-argument). Finally, the results from the questionnaire imply that argumentation might be content specific since for the same structure of the two tests, Test A had a lower Cronbach's alpha, and that was higher when Question 1 (which was heavily relying on students' knowledge on electric circuits) was removed. The hypothesis that argumentation is context specific is also supported from findings in previous studies (e.g. Means & Voss, 1996).

IMPLICATIONS

Implications for research include the design of a new tool combining the questions from both tests to see if this provides a higher internal consistency measure, and also using aspects of the questionnaire to explore (a) whether argumentation is context specific, and (b) that deciding which is a convincing argument is a higher sub-skill. Since the findings from this study suggest that choosing a convincing argument from a list of given arguments is more difficult that constructing an argument, implications for practice include finding ways to support students when deciding upon convincing arguments, since this is a skill useful in their everyday life.

TRACING OF STUDENTS' SCIENTIFIC ARGUMENTATION QUALITY

Hanife Hakyolu[1] *and Feral Ogan-Bekiroglu*[2]

[1] Dogus University
[2] Marmara University

Abstract: The study of argumentation is still a young field and more research needs to be carried out on students' argumentation quality. Therefore, the purpose of this study was to examine the quality of students' argumentation and to find out how their argumentation quality changed as their involvement in scientific argumentation increased. Case study design was guided the research. The participants of the study were 13 senior pre-service physics teachers, four of whom were females. Argumentation sequences were implemented in the methods course and lasted six weeks including two subjects, i.e. kinematics, and heat and temperature. Data were collected via students' worksheets and video recordings made during the argumentations. The current study concludes that students' argumentation quality does not increase as the number of argumentation and their involvement in argumentation increase. Second, if students have familiarity with the concepts that are argued on, they can reach the highest quality level of argumentation although they do not have any experience with argumentation process in their previous instructions. Third, changing of subjects in argumentation may get students' interest and thus affect their quality of argumentation. Fourth, concepts that argumentation is founded on can influence argumentation quality. Finally, there is no consistency in students' argumentation quality through argumentation sequences when content as well as context of argumentation change in each sequence. This study has implication of presenting the changes in students' argumentation quality in scientific argumentation sequences.

K*eywords*: Argumentation, argumentation quality, physics, case study, qualitative analysis.

BACKGROUND AND PURPOSE OF THE STUDY

The need to educate students and citizens about how we know and why we believe requires a focus on 1) how evidence is used in science for the construction of explanations, and 2) on the criteria used in science to evaluate the selection of evidence and the construction of explanations (Duschl & Osborne, 2002). "It is an argument that we are likely to find the most significant way in which higher order thinking and reasoning figure in the lives of most people" (Kuhn, 1992, p. 156).

The practice of argumentation means the sociocultural activity of constructing, presenting, interpreting, criticizing, and revising arguments (Duschl & Osborne, 2002; Johnson, 2000; Leita˜o, 2000; van Eemeren et al., 1996). When constructing an argument, individuals consider both sides of the issue, explain aspects of the problem that are anomalous to their existing conception, and must be confronted with the discrepancy between their point of view and the alternative (Nussbaum & Sinatra, 2003). Research on argumentation in science education has expanded and intensified considerably over the past two decades (Sampson & Clark, 2008). However, the study of argumentation is still a young field and more research needs to be carried out on students' argumentation quality. Therefore, the purpose of this study was to examine the quality of students' argumentation and to find out how their argumentation quality changed as their involvement in scientific argumentation increased.

RATIONALE

Reviewing of the literature revealed that only a few studies have traced students' involvement with argumentation. Kuhn, Shaw and Felton (1997) states that if both the numberof argumentation and intervention time are raised, the quality of participants' argumentation increases. When children engage in such a process, and support each other in high-quality argument, the interaction between the personal and the social dimensions promotes reflexivity, appropriation, and the development of knowledge, beliefs, and values (Erduran, Simon & Osborne, 2004). The context and content of argumentation affect participants' argumentation quality (Duschl & Osborne, 2002; Kelly, Druker & Chen, 1998). Crossa, Taasoobshirazib, Hendricksc and Hickeya (2008) present association between the systematic contribution of quality argumentative statements and the demonstrated increased understanding of the scientific concepts through increased scores. This current study would contribute to the literature toward a better understanding of how students' quality of argumentation changes as they are arguing about scientific claims.

METHODOLOGY

Case study design (Stake, 1995). was guided during this research in order to investigate the relationship between quality of argumentation and students' involvement in scientific argumentations.

Participants and Settings

The participants of the study were 13 senior pre-service physics teachers, four of whom were females. Participants of the study had completed all the necessary physics courses. The participants had been taught in traditional environments in their courses until the methods course and not had any experience with argumentation as a teaching strategy. It was the first time that the participants were being a part of argumentation context in the class.

Instructional Context

Argumentation sequences were implemented in the methods course and lasted six weeks including two subjects, i.e. kinematics, and heat and temperature. The duration of each sequence was approximately 50 minutes. Argumentations in the first three weeks were related to kinematics.

Since the preservice teachers had completed all of their physics courses and had previous knowledge of the physics subjects, the aim of the instruction was to provide opportunities for them to involve in argumentation process and to argue about scientific concepts instead of teaching physics.

Table 2 presents content, related physics concepts and context for each argumentation. The context and content of argumentation affect participants' argumentation quality (Duschl & Osborne, 2002; Kelly, Druker & Chen, 1998). For these reasons, different contents, contexts and concepts of argumentations were implemented. Argumentation worksheets were distributed to the students at the beginning of each sequence. The participants argued with each other in groups and then they shared their ideas as well as their supports with whole class. Meantime, they wrote their explanations in their worksheets.

Data Collection Methods

Data were collected via students' argumentation worksheets and video recordings made during the argumentations. Argumentation worksheets that measured several concepts such as velocity, speed, projectile motion, free fall, air friction, expansion, temperature, heat, buoyancy force, gases and pressure, included open-ended questions about topic. Mostly, these worksheets included question of interpretation in order to be connected with students' experiences easily and to increase their participation. The participants and the instructor were videotaped during the instruction. Students' voice records and videotapes were transcribed into writing documentations for coding as well as written arguments.

Data Analysis

Clark and Sampson (2008)'s model was used to code arguments and analyze the students' quality of argumentations. Their model was chosen because of its comprehensibility and was showed in Table 1. Coding was done by two researchers and repeated until agreement was reached. Quality level of argumentation was determined in terms of the number and quality of rebuttals in the argumentation. For example, Level 1 means that argumentation involving a simple claim versus counterclaim with no grounds or rebuttals and Level 5 means that argumentation involving multiple rebuttals and at least one rebuttal that challenges the grounds used to support a claim.

Table 1: *Coding of argumentations' quality*

Quality Level	Quality Characteristics of the Discourse
Level 5	Argumentation involving multiple rebuttals and at least one rebuttal that challenges the grounds used to support a claim
Level 4	Argumentation involving multiple rebuttals that challenge the thesis of a claim but does not include a rebuttal that challenges the grounds used to support a claim
Level 3	Argumentation involving claims or counterclaims with grounds but only a single rebuttal that challenges the thesis of a claim
Level 2	Argumentation involving claims or counterclaims with grounds but no rebuttals
Level 1	Argumentation involving a simple claim versus counterclaim with no grounds or rebuttals
Level 0	Non-oppositional

In our study we used this coding scheme that is developed by Clark and Sampson (2008). There is an example for coding argumentation quality of Level 3 showed as below:

Example for Level 3 coding:

Teacher:	People who are making Wing-Suit sport, must get down to the ground safely. How can they provide this safety?
Student A:	They can use parachute (**claim 1)**.
Student B:	or they can get down over the sea.
Student A:	But, water is behaving as concrete after a specific height (***rebuttal against thesis****)*.I think, they should open their parachute from sepicif heigh from the ground (**claim 2**). We shouldn't do anything that we did while speeding (**claim 3**), for rexample, we need to take wind behind of us in order to speed up, however, we need to go through the wind now (**support 1**).

Table 2: *Content, concepts and context of argumentations.*

	Argumentations					
	First	**Second**	**Third**	**Fourth**	**Fifth**	**Sixth**
Content	Motion of a car	Children throwing stones in a pole	Flying sportsmen wearing wingsuits	Decision about the most efficient thermometer	Mechanism of a hot-air balloons	Finding a correct theory for each phenomenon
Concepts	Velocity, speed	Projectile motion	Free fall, air friction	Expansion, temperature, heat	Buoyancy force, gases, pressure	Heat, energy, temperature
Context	Explanation for a phenomenon	Selection of a scientific claim	Prediction, observation, explanation	Controversial dialogues	Designing and comparison of a vehicle	Matching of a theory with a phenomenon

RESULTS AND DISCUSSION

Table 3 shows the students' quality of argumentations. According to the table, it is not possible to mention either a constant increase or decrease in the students' quality of argumentations from the first argumentation through the last one because of different content, concepts and context of argumentations. . This result in a contradiction with the results of Kuhn, Shaw and Felton (1997) who found that if both the number of argumentation and intervention time are raised, the quality of participants' argumentation increases. This contradiction may be resulted from different content, concept and context of argumentations. Another finding is that majority of the students were able to reach Level 5 and produced multiple rebuttals in their arguments although they had not required constructing argumentations in their previous teaching and learning experiences. The reason for this finding might be that the students had previous knowledge of physics concepts that they argued about. This conclusion is in line with the results of other researchs. For instance, Crossa, Taasoobshirazib, Hendricksc and Hickeya (2008) reported that students tended to feel more comfortable and be more competent in arguing about concepts when they were sufficiently knowledgeable about that subject.

Since the subject of the argumentation changed from kinematics to heat and temperature after the third argumentation, within analyses were done in the first three argumentations and in the last three argumentations separately. Table 3 also illustrates that the number of Level 5 was highest in the first and fourth argumentations. In other words, when the students started to argue about new subjects, they could create more quality rebuttals. The students might start to the new subject with enthusiasm and then they might loose their interests as they more argued about the same subject although the concepts in the argumentation were not the same. Most of the students' quality levels of argumentation were low during the second and fifth argumentations comparing to the previous ones. For example, the quality level of Student 5's argumentation decreased from 5 to 0 from the first argumentation to the second argumentation and increased to 4 during the third argumentation. In addition, Student 7's argumentation quality reduced from Level 5 to Level 2 from the fourth argumentation to the fifth argumentation and rose to Level 5 again during the sixth argumentation. This result may come from the concepts of argumentations. In the second argumentation, the students gave their answers by depending on the formulas. Hence, they did not need to discuss about the various situations. In the fifth argumentation, the students struggled with arguing about the concepts of buoyancy force and pressure which the students found hard. When the students were analyzed individually, it was realized that there was no consistency in the students' argumentation quality throughout the argumentation sequences. For instance, even though Students 1, 4, and 7 could achieve Level 5 three times through six argumentations, they could not demonstrate any opposition and stayed in Level 0 one time. Since the content and context of each argumentation was different, it is not possible to relate the quality of argumentation with either content or context of argumentation.

Table 3*: Quality of argumentations*.

	Argumentations					
Students	**First**	**Second**	**Third**	**Fourth**	**Fifth**	**Sixth**
Student 1	Level 5	Level 0	-	Level 5	Level 3	Level 5
Student 2	Level 0	Level 0	Level 0	Level 0	Level 4	No participation
Student 3	Level 3	No participation	-	Level 5	Level 4	Level 5
Student 4	Level 5	Level 0	Level 4	Level 5	Level 5	-
Student 5	Level 5	Level 0	Level 4	Level 3	-	Level 0
Student 6	Level 0	No participation	Level 3	Level 5	Level 1	Level 0
Student 7	Level 5	Level 0	Level 3	Level 5	Level 2	Level 5
Student 8	Level 2	Level 0	-	Level 5	Level 4	Level 4
Student 9	Level 5	Level 0	Level 4	Level 5	Level 0	-
Student 10	Level 3	Level 0	Level 5	Level 5	Level 2	-
Student 11	Level 4	No participation	Level 5	Level 0	Level 3	Level 0
Student 12	-	No participation	Level 0	No participation	Level 0	Level 0
Student 13	-	Level 0	Level 1	Level 0	Level 3	Level 0

CONCLUSION AND IMPLICATION

The current study concludes that students' argumentation quality does not increase as the number of argumentation and their involvement in argumentation increase Second, if students have familiarity with the concepts that are argued on, they can reach the highest quality level of argumentation although they do not have any experience with argumentation process in their previous instructions. Third, changing of subjects in argumentation may get students' interest and thus affect their quality of argumentation. Fourth, concepts that argumentation is founded on can influence argumentation quality. Finally, there is no consistency in students' argumentation quality through argumentation sequences when content as well as context of argumentation change in each sequence.

This study has implication of presenting the changes in students' argumentation quality in scientific argumentation sequences.

THE WAY THE HISTORY OF SCIENCE DISCOURSE IS EMBEDDED IN GREEK SCHOOL SCIENCE TEXTBOOKS

Krystallia Halkia[1], Kostas Exarchakos[2] and Constantine Skordoulis[3]
[1,2,3] School of Education, University of Athens

Abstract: The history of science discourse can contribute to two basic aims of science education, those of learning science and those of learning "about science". In the relevant bibliography the main arguments supporting the inclusion of history of science in science teaching are: students are introduced to the contemporary social issues of science and the nature of science; history of science establishes science as a result of human actions; it promotes students' meaningful learning of the subject matter; it improves their attitudes towards science, etc. This work focuses on the way the history of science discourse is presented in Greek lower secondary education (7th-9th grades) science textbooks. The textbooks under study are six: 2 Physics, 2 Chemistry and 2 Biology, as well as the corresponding student's activity packages. The research instruments are a combination of quantitative and qualitative ones. The analysis of the collected data revealed that the discourse of the history of science is limited, fragmented, superficial and in many cases literally marginalized, reflecting the authors' ideological and epistemological views about the nature of science. In most cases the course of scientific endeavor is presented as an ongoing linear progress, being the result of a unique scientific method strictly followed by every scientist. Moreover, science appears to be the product of individual scientists' efforts, while the socio-cultural context in which science is produced is usually overlooked. Finally, almost half of the textbooks reflect the idea that the origin of science lies mostly in the works of Greek philosophers, thus serving the Hellenic national narrative.

Keywords: Science education, Science textbooks, History of science, Lower secondary education

INTRODUCTION

There are numerous arguments favoring the engagement of history of science in science education. Among them is that history of science helps students to learn science, as well as to learn "about science" (Leite, 2002; Wang & Marsch, 2002). Regarding learning science, Galili & Hazan (2000) have pointed out that history of science promotes students' meaningful learning of subject matter, thus helping them to understand the concepts and processes of science (Wang & Marsch, 2002). As far as learning about science is concerned, history of science helps towards humanizing science, improves students' attitudes towards science and helps them to understand the contemporary social issues related to science (Leite, 2002) or to deepen on questions about the nature of science (Niaz, 2000). Also, history of science when focusing on the epistemology of science shows that there is not a unique and specific scientific method, but a number of parameters (goals, interests, motives, etc.) that influence the way scientists work when they "do science" (Chalmers, 1982; Knein, 2001).

Another argument in favor of using history of science in science education is that it can help towards the conceptual change of students' alternative ideas, especially those that resemble to the ones scientist of the past held (Wandersee, 1985; Seroglou et al., 1998, Galili & Hazan, 2000).

On the other hand, school science textbooks are considered to be one of the most powerful educational medium in imposing their meaning on students' minds. They are one of the agents that socialize students (Knain, 2001) and they are institutionally defined. The texts in school textbooks have greater "authority" (Olson, 1989) than other texts open for meaning-making. Each student interacts with the text, and constructs his or her own meaning in the social process of reading. The interpretive power of pupils is limited by the closure and institutional authority of textbooks (Kalmus, 2004). Thus, the way history of science is recontextualized and presented in school science textbooks is very crucial for the construction of the image of science in students' minds.

The purpose of this work is to trace the way the history of science discourse is presented in Greek science textbooks of lower secondary education. Such a discussion may contribute to developing generally accepted criteria in designing future educational texts.

THE GREEK EDUCATIONAL CONTEXT

The context in which lower secondary education science textbooks are functioning in Greece is characterized by: different science areas (physics, chemistry, biology) are taught as distinct subjects (e.g. Physics, Chemistry and Biology) and not in an integrated way (e.g. Science). Moreover, for a specific grade and a specific science subject, only one textbook is authorized by the Greek Institute of Education to be distributed to all Greek students. Thus, the "authority" of these textbooks is great; confining the way students and teachers can interpret the kind of image of science they present. For that reason it is very important to trace the way the history of science discourse interacts with science discourse in constructing the image of science presented in Greek science textbooks.

METHODOLOGY

The research question: To what extent and in which ways is the history of science discourse incorporated in Greek science textbooks of lower secondary education?

There was no sampling, as the research considered all Greek lower secondary education science textbooks, i.e. six (6) textbooks: 2 physics (ph8, ph9) textbooks (grades 8 and 9), 2 chemistry (ch8, ch9) textbooks (grades 8 and 9) and 2 biology (b7, b9) textbooks (grades 7 and 9) and the corresponding student's activity packages accompanying each textbook (Table 1).

Greek lower secondary school						
	Subject			No. of Textbooks (activity packages)		
grades	Physics	Chemistry	Biology	Physics	Chemistry	Biology
7th (12 -13 ys)	-	-	+	-	-	1(1)
8th (13-14 ys)	+	+	-	1(1)	1(1)	-
9th (14-15 ys)	+	+	+	1(1)	1(1)	1(1)

Table 1: Greek science textbooks

The research instruments: The research instruments were a combination of quantitative and qualitative ones. Specifically, a quantitative instrument was developed to explore the status that the history of science discourse posses in Greek science textbooks (Table II). In addition, a part of qualitative instrument developed by Leite (2002) was used to explore the way the evolution of science is presented. The latter one has been enriched by two more indicators (mention of a specific scientific method, and mention of Greek history or mythology) as well as some numerical descriptive factors (Table 2).

RESULTS

All Greek school science textbooks are designed according to a more or less similar pattern (macro-structures). Specifically, they are shaped according to specific modes, like:
A) a core “text”, which is the main source of study for students. The core “text” mainly consists of (micro-structures): a) written texts; b) pictorial (visual) representations (tables, graphs, experiments, etc.); c) questions and exercises and d) activities. All these are considered to be obligatory requirements for the students.
B) a supplement “text” which is considered to be open to any student who would like to be more engaged with issues related to the subject under study. The supplement “text” mainly consists of: a) pictures and captions referring to scientists or technological devices; b) insets referring to interdisciplinary or STS issues; c) colored pages which are used either as an introduction to a chapter, or to present a short science story or to additional activities; d) appendices which in biology textbooks refer to history of science events in chronological order.
In most cases, science textbooks of the same subject have been written by the same group of authors. Only the group of authors for the two chemistry textbooks (ch8 and ch9) is totally different. Head of each group is usually a staff science university member.
The quantitative (descriptive) analysis of the Greek science textbooks in an attempt to trace the presence of the science discourse is depicted in table II. Most rows of the table, especially those referring to the analysis of written texts, present the sum of all references to the science discourse as number of pages and the corresponding percentage (%). However, some others, which refer to the analysis of specific incidents having an autonomy (e.g. images, activities, insets etc.), present the sum of all incidents as number of references and the corresponding percentage (%).

School textbooks and activity packages						
Modes (Macro-structures)	ph2	ph3	ch2	ch3	b1	b2
A) Core “text”						
a) written text no. of pages (% total)	4,5p (2,8%)	5p (3,3%)	0.7p (0,7%)	0,75p (0,8%)	-	2,8p (1,9%)
b) pictorial (visual) representations (tables, graphs, experiments)	-	-	-	-	-	-
c) questions and exercises	-	-	-	-	-	-

Table 3 (part of Leite's table II): Analysis of the type and organization of the historical information

CONCLUSIONS AND IMPLICATIONS

Data analysis (Tables 2 and 3) showed that there are differences among books; the presence of history of science is greater in physics textbooks than in chemistry or biology textbooks but, at the same time and more problematic. However, despite of their differences, the authors of Greek science textbooks in lower secondary education do not consider the history of science discourse as a vital (integral) part of science discourse. They do not seem to consider that it helps students to understand the content of science and the nature of science. This is quite obvious in the way the history of science discourse is distributed in different parts (modes) of the science textbooks. It appears mainly in the supplementary "text", which students may not necessarily study. In addition, its presence is in most cases fragmented, minimal, superficial and out of context, something which is supported by the findings of other researchers too (Slobs & Travers, 1996, as it is cited by Leite, 2002). Thus, instead of being an interpretative tool to understand science it is a decorative element in science textbooks.

Science appears to be the product of individual scientists' efforts, while the socio-cultural context in which science is produced is usually overlooked. The way the history of science discourse is presented (the images of scientists of the past and the rhetoric used) seem to support the idea that they are there to attribute respect to our science ancestors. Of course, it presents the humanistic face of science, but at the same time it imposes a kind of individualism and idealism too. Phrases like "Faraday invented the concept of field", "Coulomb succeeded to answer the question…", "Joule showed that…", Öersted invented by accident that…", "Amber claimed that…", "Rutherford discovered that…" are very common especially in Physics textbooks and are used to verify final results or statements. The authors prefer to use a mathematical approach to reach the final results instead of the path of syllogisms which drove to these results.

The evolution of science is presented as linear and straightforward, without backs and forth's. In all textbooks, a unique and very specific scientific method is presented as the only method which gives answers to every scientific question and which ought to be followed by every scientist. Thus they support a positivistic and, in many cases, a deterministic view too.

In the supplement "text" (insets and colored pages), very often a short science story is presented. This story usually is based in science anecdotes (mythological descriptions of science events), which emerged when rewriting science to support the science narrative. Also, in about half of the textbooks, the origin of science lies mostly in the works of Greek philosophers, thus serving the Hellenic national narrative. In these cases, the majority of chapters begin with a brief history on the specific field, starting either from Greek mythology or from the ancient Greek philosophers and their views on the specific subject. This can be considered as underlying (latent) manifestation of a common ideological theme regarding the pioneering role of the Greek thinkers. There are few cases though, where they present origins from the works of Babylonians or the Chinese thinkers.

Based on the above it seems that the history of science discourse is embedded, in Greek science textbooks of lower secondary education not as an interpretative tool for understanding today's science, but rather as a decorative element serving to support stereotypes and functioning as an authoritative discourse for persuading students to accept final data and conclusions.

Having in mind that in Greece there is only one textbook for each science subject, we understand the great ideological power it has over students' and teachers' minds. Based on the above results, this power is not on the side of science and the nature of science.

How does the Content-related Quality of Students' Statements Influence the Learning Outcome?

Rebecca Knobloch[1] *and Maik Walpuski*[1]
[1]University of Duisburg-Essen

Abstract: In this study videos of small-group experimentation are analysed with two aims. The first aim is to develop an instrument to analyse the quality of content-related statements in student-student communication. The second aim is to investigate the influence of the quality of content-related statements in smallgroups on the learning outcome. For this purpose, existing video data of a preceding research project on experimental inquiry tasks in chemistry education were reanalysed in a first step.
On basis of this reanalysis the instructions for the smallgroups were revised in order to achieve a higher grade of communication from a content-related viewpoint. The learning effectiveness of the revised instructions was examined in an intervention study (N = 192 students) using video analysis and content-related achievement tests. The results of the intervention study showed that the revised instructions were able to enhance the quality and amount of statements. Furthermore the optimisation of the communication quality led to a higher learning outcome.

Keywords: communication – small-group work – video analysis

BACKGROUND

In typical German science lessons teachers dominate the communication (Sumfleth & Pitton, 1998). The percentage of teachers' speech is about 60-85% in many regular chemistry lessons. It has, however, already been proved that especially student-student communication can lead to a deeper examination of the content (Rotering-Steinberg, 1995). According to this, the student-student communication should be promoted.
This study deals with the student-student communication in smallgroups in order to investigate possibilities to increase the quality and amount of students' subject-related statements. The first aim of the study is to develop an instrument to analyse the content-related quality of students' statements. Furthermore, the influence of the quality of content-related statements on the learning outcome is investigated. Analysing small groups is suitable for this purpose because there is an increased rate of student-student interaction compared to classroom instruction.
Both aims lead to the following research questions:

1. Which characteristics of content-related statements can be found analysing the statements of successful and less successful smallgroups (related to the learning outcome) in scientific inquiry phases?
2. Is it possible to increase the quality and amount of statements by optimised instructions of content-related communication situations?
3. Is it possible to enhance the learning outcome by the improvement of the small group communication?
4. Does the altered communication behaviour persist when the corresponding instructions are omitted?

Studies dealing with the quality of subject-specific communication in small groups and analysing the influence of the quality of statements on the learning outcome are rare. The few existing systems for categorising students´ statements are insufficient to investigate the quality of the statements in detail, as they focus only on single aspects (e.g. von Aufschnaiter, Erduran, Osborne, & Simon, 2008). As a result, a new category system had to be developed. Already existing instruments were considered for the development.

In a first step a measure for the content-related quality of statements was developed. For this purpose an existing category system for video analysis used for describing the complexity of tasks in classroom situations (Neumann, Fischer, & Sumfleth, 2008) was adapted. The category system describes the *complexity* of statements by distinguishing them into *facts, relations* or *concepts*. In addition to this, a model of competence to evaluate the German national educational standards was adapted (Walpuski, Kampa, Kauertz, & Wellnitz, 2008). In this model the complexity is varied systematically to construct test items of a defined difficulty. In addition to the *complexity*, *cognitive processes* (reproduction, selection, organisation, integration) are a second dimension in this model. The cognitive processes define which cognitive demand is needed to solve the task. With this model of competence the achievement of students in paper-pencil test can be described. Since the present project also addresses students' achievement, the basic assumptions of the competence model were adapted for the video analysis. We assume that – in addition to the complexity and the cognitive processes – the correctness of the statements is also relevant for the quality of content-related communication.

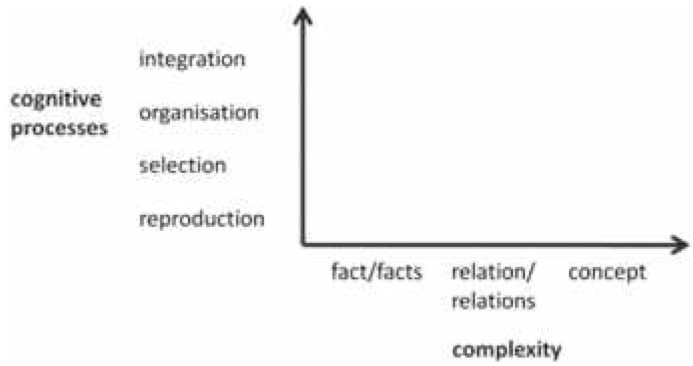

Figure 1: Model for estimating the quality of subject-specific statements (adapted from Walpuski, Kampa, Kauertz, & Wellnitz, 2008)

METHOD

As already mentioned, the study is divided into two parts. In the first step, existing video data of a preceding research project on experimental inquiry tasks in chemistry education (Walpuski, Wahser, & Sumfleth, 2008) were reanalysed to check whether the assumed characteristics for successful and less successful small groups can indeed be found. In this context, success refers to the learning outcome of the small-groups. We assume that successful groups are characterised by more correct statements on a higher level of complexity demanding higher cognitive processes. To test the developed category system 30 videos of 15 successful groups and of 15 less successful groups were reanalysed using the program videograph®. The analysis was used to calculate correlations between the measures from video analysis and performance tests.

Due to the fact that these correlations do not prove any causality or direction, an additional intervention study was needed. For that reason, in a second step, it was investigated if it is possible to increase the quality and amount of subject-specific statements by modified instructions for the small-group work. To prove the causality, additional analyses were carried through as to whether the learning outcome could be enhanced at the same time. A control group did not receive any intervention. In the school year 2009/2010, 48 small groups (4 students each) were videotaped over five lessons.

Table 1: Treatment groups

	lesson 1	lesson 2	lesson 3	lesson 4	lesson 5
control group	unmodified instructions	unmodified instructions	unmodified instructions	unmodified instructions	unmodified instructions
intervention group	unmodified instructions	revised instructions	revised instructions	revised instructions	unmodified instructions

The topic of the small-group work was acids and bases in the 7th grade of secondary schools (high-level). As control variables the cognitive abilities test (Heller & Perleth, 2000) and a test on scientific procedures (NAW) (Klos, Henke, Kieren, Walpuski, & Sumfleth, 2008) was conducted. In addition to this, a test on chemical content knowledge was used (pre-test and post-test) as well as a test on cross-linked content knowledge (triad test). The triad test was used only in the post- and the follow-up-test, because cross-linked was not expected in the pre-test. Additionally, the small-groups were video-taped and in each lesson a short test on content knowledge, referring to the contents of the corresponding lesson, was conducted (see Table 2).

Table 2: design and instruments of the intervention study

pre	accompanying	post and follow-up
• test on chemistry knowledge (Walpuski, 2006) • test on scientific procedures (NAW) (Klos et al., 2008) • cognitive abilities test (Heller & Perleth, 2000) • last grade in chemistry • repetition of classes	• test on chemistry knowledge after each lesson (Walpuski, 2006) • videos 	• test on chemistry knowledge (Walpuski, 2006) • test on scientific procedures (NAW) (Klos et al., 2008) • test on written communication of relations (adapted from Neuroth, 2002)

The intervention and the control groups were balanced based on students´ cognitive abilities and previous knowledge, which were assessed beforehand.

Video analysis

In order to analyse the videos, a category system was constructed. This category system (see Figure 2) contains the correctness and the complexity and cognitive processes.

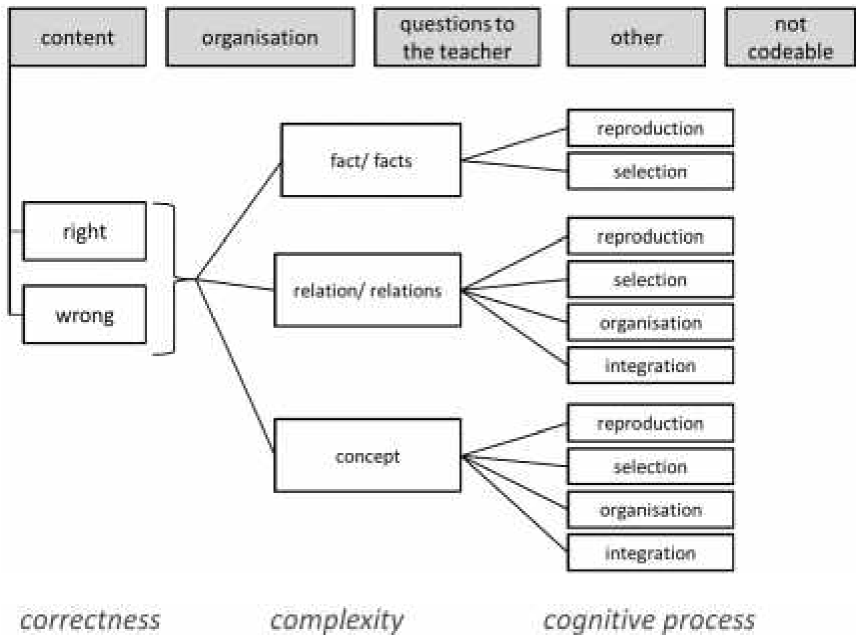

Figure 2: Cut-out of the category system, categories shown in grey, subcategories of the content-related statements in white

To test the category system 10 videos of the reanalysis were coded turn-based by two raters independently using the program videograph®. The category system distinguishes the main categories: content, organisation, questions to the teacher, other and not codeable.
All content-related statements fall into the category *content*. Furthermore, these statements are analysed regarding their correctness, complexity and cognitive processes (see Figure 2). As already mentioned, the complexity describes the amount of information and their linkage, while the cognitive processes define which cognitive demand is needed.
Both the cognitive processes and the complexity are described in the following examples:
Reproduction of fact/facts: “It´s like yesterday, the solution is red.”
Integration of relation/relations: “If the red cabbage juice turns red, when adding hydrochloric acid, then all acid solutions should turn red.”
The first example is classified as *reproduction of fact(s)* because just an observation is described, which the students already know from the previous lesson. The second example is assigned to the category *integration of relation(s)* because it is a generalisation (integration) and an “if-then relation” is stated.
To analyse the characteristics of successful and less successful small-groups, the data of the 30 videos were analysed with the statistical software PASW18 ®. To compare the amount of turns, the number of turns was analysed related to minutes.

RESULTS AND CONCLUSIONS

Results of the reanalysis

In the first step of the study, two trained raters independently coded 10 videos. The results of the interrater-reliability are between $.82 < \kappa \leq .99$. The amount of agreement of the category system can be regarded as very good. The assumed characteristics for successful and less successful small groups were found in the reanalysis. The successful groups state more correct ($p < 0.01$) content-based statements than the less successful groups. Regarding the correct content-related statements only, the successful groups reveal a higher rate of statements in all cases. These differences are significant in the higher cognitive processes on a level of relations ($p < 0.05$ and $p < 0.001$) (see Figure 3). This means that the assumed characteristics for successful and less successful small groups were found in reanalysis in the predicted way. This is also an indication of the validity of the category system.

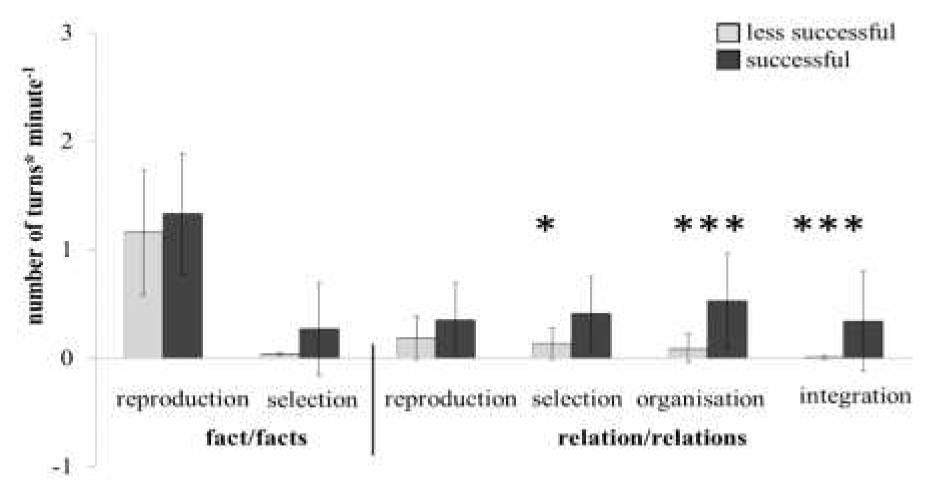

Figure 3: number of turns per minute of the content wise statements, which are correct (mean value+SD)

Results of the intervention study

The sample of the intervention study consisted of 192 students of the 7th grade of secondary schools at a high-level. As some students were not present at the pre or the post-test, only the data from 186 students were used for the pre-post analysis. Furthermore, 7 videos of the 240 videos were not included in the analysis of the video data, because there were only two students in the small-group work present instead of four students or because the audio material was inadequate.

The video analysis showed that there were no significant differences concerning the main categories between the groups. As especially the content-related statements are of particular interest, only the detailed results of the content-related statements will be presented in the following.

The analyses concerning the correctness of the content-related statements show no significant differences, but the intervention group tends to make more correct and less false statements. On a level of facts no differences between the groups could be detected. In contrast, on the level of relations there are highly significant differences for all cognitive processes ($p<0.001$) (see Figure 4). The intervention groups make more statements belonging to the categories *reproduction of relation(s)*, *selection of relation(s)*, *organisation of relation(s)* and *integration of relation(s)*.

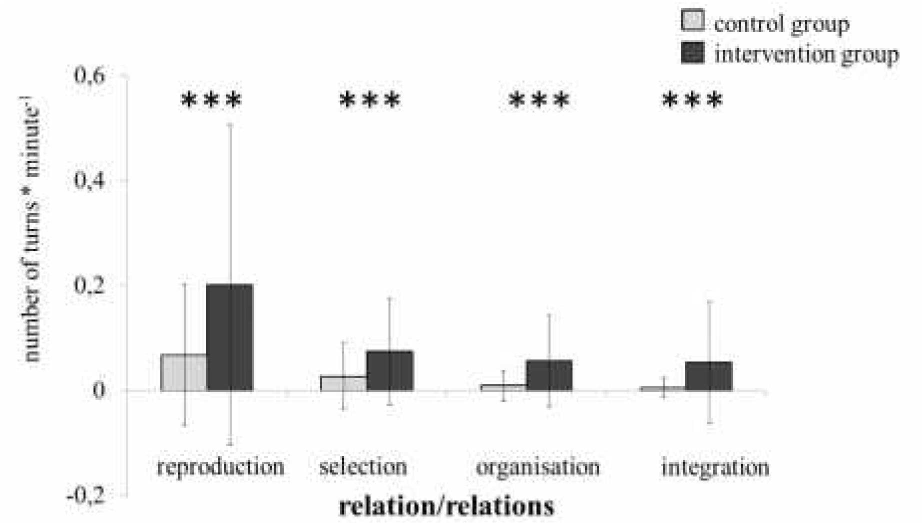

Figure 4: number of turns per minute on a level of relations (mean value+ SD)

Analysing only the fifth lesson, where no intervention took place, there are still differences between both the treatment groups concerning the complexity and cognitive processes of the content-related statements. As shown in Figure 5, the intervention group makes more statements in the categories *reproduction of relation(s)* ($p<0.05$), *selection of relation(s)* ($p<0.01$), *organisation of relation(s)* ($p<0.01$) and *integration of relation(s)* ($p<0.05$).

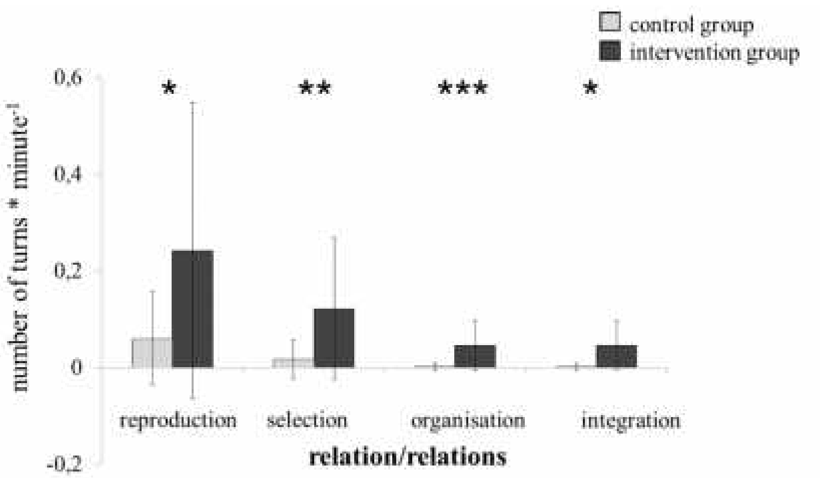

Figure 5: number of turns per minute on a level of relations of the fifth lesson (mean value + SD)

The results of the paper-pencil tests show no significant differences compared to the control group concerning the multiple-choice-test, which tests mainly factual knowledge. But the intervention group is very highly significant ($p < 0.001$) better in the triad test, which tests cross-linked knowledge with open-ended questions.

DISCUSSION AND CONCLUSION

The results of the reanalysis show that there is a close connection between students' learning achievement and the quality of content-related statements in smallgroup work. The assumed communication characteristics of successful groups could be proven by the empirical data. Since these correlative relations cannot reveal any causal direction, an intervention study was conducted. In this study the quality of content-related statements was supported by modified instructions, which were meant to stimulate statements on a level of relations.

The results show that the revised instructions actually increased the quality and amount of content-related statements. The intervention group made more statements of the categories *reproduction of relation(s), selection of relation(s), organisation of relation(s)* and *integration of relation(s)*. Furthermore, the instructions enhanced the more complex cross-linked knowledge. Concerning the factual knowledge, there are no significant differences between the control and the intervention group. Nevertheless, both groups had a significant gain of knowledge. Differences can be shown in the test on cross-linked knowledge where the intervention group performs significantly better. Therefore, it can be concluded that the learning outcome, at least concerning the cross-linked knowledge, can be enhanced by improving the small group communication. Furthermore, in the fifth lesson still significant differences in the amount of stated relation could be detected although there was no intervention. This can be interpreted as a retention effect of the intervention.

Nevertheless, the study enables an insight in the connection of learning achievement and the quality of the stated content. A further benefit of the study is an instrument which ascertains the quality and quantity of content-related statements economically. In practice, the study submits an optimisation of the small-group work with interaction boxes with the topic acids and bases.

Study of the interrelationship between students' arguments and features of tasks in science classes.

Aikaterini Konstantinidou[1],Marina Castells[1],Jose Mª Cerveró[1]
[1] University of Barcelona

Abstract: From previous studies we have identified types of arguments that students use when they solve problem-tasks in science classes. In this paper, we will focus on the way the features of the tasks determine the type of argument that students use. It is a qualitative study that gives a deep understanding of students' scientific conceptions, and how students interrelate their ideas with the types of arguments they use in a science class situation of dialogue in small groups. Our analytical framework is mainly based on the Theory of the Argumentation of Perelman, and the schemes for presumptive reasoning of Walton. We will complement those schemes with some of Aristotle's "topoi". With this analytical framework we have analyzed several transcribed dialogues of students during open activities in a secondary school, and recognized the argument and premises that students use in their arguments. A result from our study is that tasks influence the argumentative schemes and the premises used by students in a different, and sometimes unexpected, way. This depends on specific features of the tasks, but also on the personal interpretation that students make, which could be related to their ideas and misconceptions. The process of analysis enlightens our understanding of their science conceptions related to the scientific content, and also important implications for the training of the teachers that can be drawn.

Keywords: Argumentation, Science's Misconceptions; Secondary Education

BACKGROUND, PURPOSE AND FRAMEWORK

Relevant to the aim of our research, there have been attempts to identify general strategies of reasoning that were not related to a specific content of the questionnaire, or the interview commonly used in research about the science conceptions of students (Andersson, 1986; Guidoni, 1985, 1990; Viennot, 1996; Castells & Pintó, 2000). These works contribute our thinking in the way that beneath the specific forms of reasoning of the students, there can be found some common or general ways of reasoning or patterns of arguments or schemes. From those studies, we suppose now that the image we have to have of the science of children can't be as simple as at the beginning of this research line could be supossed and linked not only to ideas or concepts but also related to patterns of reasoning students acquire during their live into and outside the school. In the last decades, numerous studies have focused on the analysis of argumentation discourse in educational contexts; among others, Driver, Newton, & Osborne, 2000; Jimenez-Aleixandre, Burgalló & Duschl, 2000; Zohar & Nemet, 2002; Erduran & Jimenez-Aleixandre, 2007; Buty et Plantin, 2008). In relation to research on argumentation great influence has been contemporary's theories of argumentation, especially Toulmin's (1958), who apart from the theoretical part of his work, has provided with his schematical representation of an argument, which has been a useful and practical tool to analyse and to teach to build arguments in science classes' context. Even less research has been focused on the interrelationship between the conceptual comprehension of the students and their argumentation (Von Aufschnaiter, 2008) despite the fact that nowadays science education agrees to introduce argumentation in science classes and also to foster dialogical attitudes (Scott et Al. 2006) and collaborative capabilities in the students.

The *Purpose* of this work is to study with detail the possible relationship between the argument schemes used by the students in small group discussion often related with misconceptions in science and the features of the qualitative tasks that we propose to them.

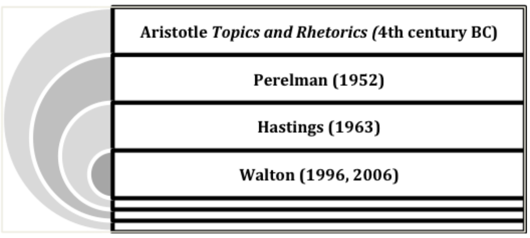

Figure 1

Our *Framework* is mainly based on the Theory of the Argumentation of Perelman (1952) and completed with the schemes for presumptive reasoning of Hastings (1963), Walton (2006, 2008) and with some of Aristotle's "topoi" (III BC). (figure 1)

The mentioned authors; provide argument schemes and types of premises, which we expect to find in the discussions with the students, considering that their arguments are mainly not deductive, but of presumptive nature. These theoretical bases come mainly from the field of Philosophy and they have not been used in science education research, except for few studies (Jimenez-Aleixandre, 2003; Duschl, 2008; Author et al., 2007; Fagundez & Author, 2008; Author, Erduran, Author, 2009 According to our perspectives, we consider an argument consisting of a thesis, one or several premises, and the scheme that allows the transference of the accepted premises to the thesis or conclusion (figure 2).

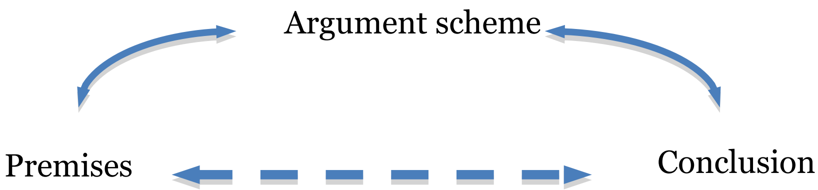

Figure 2

RATIONALE

The general approach of this work is to use the argument schemes as an instrument to understand the ideas and conceptions of students through the analysis of the structural part of the arguments, and identifying in which schema the argument is based on. With our proposal, the previous scientific ideas and conceptions of the students that, of course, has been studied during the last decades in a lot of detail in the research field of science education and psychology, are reanalysed with an argumentation focus approach, capable to characterise the types of arguments and their structural elements which are mainly used by the students, and to better understand the difficulties of the conceptual change of students, as we did in our work presented at ESERA 2009.

In this study, we go further, and in a qualitative and deep way, we try to enlighten the interrelation among fundamental elements in the conceptual development of students that will take up in a dialogical setting of science classes: features of the problems-tasks we propose to students, previous scientific ideas that students have, personal interpretation of the situations of the tasks and the argumentation schemes used by the students performing the tasks in small group. We can summarize the research questions as:

-What types of argument schemes and premises could be found in arguments of the students? Are they related to these specific tasks?
-Which features of the tasks are more relevant for its influence on the argument schemes and premises used by students and in which way?

-Which is the ‘role’ of the students’ interpretation (“visions”) of the situation presented in the task in relation with the arguments given by them? Which is the relationship between these interpretations (“visions”) and previous scientific ideas of students?

METHODS

Instruments and Sample

Four qualitative and open tasks are proposed to several small groups of students in two classes of compulsory secondary education (12-13 years old and 14-15 years old) in a public school in the metropolitan area from Barcelona. The tasks are about: *Forces related to a body holding by a pulley arrangement, Floating and sinking and Climate change; Heat conductivity* and *Galilean Relativity of motion*.

Table 1. The proposed task

Description of the task	The tasks
1. *Conceptions about forces related to a body holding by a pulley arrangement* Students have to answer if the force the child has to do is the same or different at the different positions.	In which of the three situations A, B o C the bag weights more? Why?  (adapted from Guidoni, 1990)
2. *Floating and sinking and Climate Change* A physics and social problem is presented in the form of 3 slides, one after the other with the three questions presented here.	 1. What will happen to the level of the water when the ice melts? Why? 2. Does your prediction agree with the result we show below? 3. Scientifics agree that because of the increase of temperature in the Earth as the main cause of (because) the climate change, the level of the sea will increase. Could you compare this prediction with the result of the previous experiment? If the prediction of the scientifics is correct, how do you explain this prediction taking in consideration the previous experiment of the glass and the ice?
3. *Heat conductivity* A comic presents three different children’ ideas/arguments. Students have to chose with which one they agree and why.	 With which child do you agree and why? 1. Don’t put the coat on the snowman. It will melt him 2. I don’t think that the coat will make any difference 3. It will keep him cold and stop him melting. (Osborne et al. 2004 IDEAS)
4. *Galilean Relativity of motion* A physics problem in the context of a river is phrased in a way encouraged student to see the situation from the frame of reference in motion (river). Students have to take a decision between two possible actions in relation to a two floating boxes in a river	Imagine that you are floating on a tyre in the middle of a river and not swimming. Some metres upstream there is a wooden box floating and some metres downstream is another wooden box. a) If you are floating, not swimming, will the distance between you and each box change with the time? Why? b) Imagine the tyre no longer holds you up. Which of the two boxes would you reach first? Why? (Castells, 1997)

Students neither received any instruction about argumentation nor the scientific content of the some of the proposed tasks. After writing the answer individually, students discussed in a small group (3 or 4 students) about their proposed answers and about the reasons or arguments of their answers. The dialogues were voice recorded and then transcribed.

The Analysis

The analysis mainly consists of looking for arguments in the transcribed dialogues, identifying thesis, premises and argument schemes. From our theoretical framework, we elaborate a primary list of argument schemes, and types of premises, which are our initial analytical framework. With this framework, we recognise the argument schemes and premises that students use in their arguments. From this analysis, we enlarge our initial list of schemes, using some schemes from Walton (2006, 2008), Hastings (1963) and Aristotle's Topics.
The list of argument schemes that we used is given to the following table.

Table 2. Definition of argument schemes of our analytical framework

Argumentation scheme	Definition
1. **Double Hierarchy argument (DH)** (Argumentation scheme of Perelman and Olbrechts-Tyteca 1969, p.337)	Arguers that use the double hierarchy strategy take an established series or hierarchy, one accepted by or at least familiar to an audience, and form a second series on the model of the first, in the process trying to transfer implications of order or value form the first to the second DH. DH normally expresses an idea of direct or inverse proportionality, or at least a term- to–term relation.
2. **Example/Illustration** (Argumentation scheme of Hastings, 1963, p.25) (Walton, 1996, p. 50) (Perelman and Olbrechts-Tyteca 1969, p.350)	In this scheme, the essential characteristic is the verbal formulation of a description of an aspect of reality from the presentation of typical instances, examples, or samples of reality.
3. **Quasi –logical Arguments** Argumentative scheme of Perelman & Olbrechts-Tyteca (adapted from Warnick, 1999)	They are classify Quasi-logical by comparing them to formal reasoning, with which they have something in common, but they lack of the rigor and the preciseness of logical ones.
4. **Expert opinion- From Authority (Testimony)** (Argumentation scheme of Hastings, 1963, p. 126) (Walton, 1996, p. 64)	In using this argument from authority the speaker supports his conclusions directly by presenting an authority who asserts that the conclusion is true: The process is, in effect say "X says that this is true or advisable, etc., and therefore we can infer that it is true or advisable, etc
5. **Argument from Sign to an Unobserved Event** (Hastings, 1963, p.55) (Walton, 1996, p.47)	One known even is taken as an indication of the existence of an unobserved event, attitude, state or condition. From the fact of the occurrence of the first event, the conclusion is that the second event is or was present.
6. **Argument from analogy** (Perelman and Olbrechts-Tyteca 1969, p.371) (Hastings, 1963, p. 111) (Walton, 1996, p.77)	To support a conclusion, a comparison is made between the situation under consideration and another situation. The second, analogical event is similar not on the basis of facts or circumstances, but on the basis of abstract principles; the structure of the abstract relationship of the two events is the same. The conclusion, which is drawn about the analogical event, is applied to the topic situation.
7. **Argument from correlation to cause** (Walton, 1996, p.71)	Infers a causal connection between two events from a premise describing a positive correlation between them.
8. **Argument from consequences** (Walton, 1996, p.73)	Practical reasoning in which a policy or course of action is supported or rejected because the consequences will be good or bad.
9. **Argument of ends and means** (Perelman and Olbrechts-Tyteca 1969, p.273)	Some ends appear desirable because the means to realize them are created or become easily accessible. In other words, some ends appear all the more desirable, as their realization is easy.

Process of analysis

The process of analysis with more detail consists of three steps:

- First Step: We look for arguments in the transcribed dialogues**, identifying** thesis, premises and argumentative schemes. (Due to lack of space we omit here the examples)
- Second Step: From our theoretical framework, we **categorize the argument schemes** and premises that students use in their arguments. (From this analysis, we can enlarge our initial list of schemes). (Table 3 presents some examples to illustrate our categories)
- Third Step: We try to **relate** the above categories with the special features of the problem and students' conceptions.

Table 3. Examples of students' argument schemes

Argument scheme	Example
1. **Double Hierarchy argument (DH)** *(Task 2)*	Student*: "... the surface of the raft is not sufficient to support the weight of the mammoth on the water. (...) Our solution is to increase the surface of the raft on contact with water (length and width), but not in height. The more surface has the raft, more weight is able to withstand the mammoth..."*
2. **Example/Illustration** *(Task 1)*	Student: *"In theory the sack weighs the same, but since it's nearer to the earth it weighs more, isn't it? It's as for example* ***you take the sack to the moon, we would say that there it weighs less, but it still has the same mass****. So, I would say that the sack weighs more. What happens is that the mass sis the same, but being nearer to the earth, the gravitational force is bigger."*
3. **Quasi –logical Arguments** *(Task 2)*	Student: *"I think that the water level will stay the same, because when the ice is first added to the water, displacement takes place forcing the water level to rise. As the ice melts this would counteract the displacement, but obviously the melted water would add to the volume, therefore creating a neutral effect where the water level would stay the same."*
4. **Expert opinion- From Authority (Testimony)** *(Task 1)*	Student:*"I think that when the ice melted the level of the water will increase a little because in the News at TV they say that the level of the sea will increase because the climate change."*
5. **Argument from Sign to an Unobserved Event** *(Task 3)*	Student*: When you put a coat on a snowman, then coat becomes wet, that means that the snow melts in the coat.*
6. **Argument from analogy** *(Task 3)*	Student: *"I think that the boy that is right is the third one: " It will keep it cold and stop melting it". To us (people), the coat works to keep body's temperature and not get cold; so, it will happen the same to the snowman."*
7. **Argument from correlation to cause (Walton, 1996, p.71)** *(Task 2)*	Student*: "...And more, the climate change makes that the heat arrive before and makes that the trees produce flowers before and that in February the allergies begin because of the pollen although they would have to begin at the end of March.*
8. **Argument from consequences** *(Task 1)*	Student: "*I think if the river flows down, I would go towards the box below, because it would help me also to go down. The current of the river goes down and thus it helps to go faster."*
9. **Argument of ends and means** *(Task 1)*	Student: "*I think that of the river has a current down stream, I would have done towards the bow that is downstream… because it would help me to go downstream*".

Following, we present two fragments of transcriptions taken from one of the proposed problems in order to illustrate one aspect of the analysis, the importance of student personal interpretation of the situation of the task.

Transcript task boy supporting a bag by a rope	Personal interpretation of students
Student 1: … *I think it weighs the same because it is the same bag, except in the beginning he can hold it better because he feels stronger and finally he get tired a bit with the bag and that's why the bag is lower.* Student 2: *I agree that in A the bag weights more*	Student's 1 interpretation is based on the tiring subjective sensation that means a possible personal effect related with the view of the three pictures as a process A→B→C. Student's 2 interpretation is based on the position of the bag and its distance with the

because the further up the force of gravity the greater it tends to go down, and that's why the boy stretches it more...	ground. (geometrical view)

The majority of the students answer correctly the question about the weight, but they add comments about the force that the boy has to do that depend on their personal interpretation of the task.

Different interpretations of the task 1

1.**They "see" the different distance with a ceiling or the floor in the three drawings.**
The main types of argumentation schemes that are used in this interpretation is DH arguments.
In this interpretation, students' conceptions have mainly to do with "gravity increases with height" and "gravity decreases with height".
2.**They "see" the three drawings as a sequential process**
The main type of argumentation scheme that is used in this interpretation is the DH argument, taking account the parameter of time.
3.**They "see" the existence of a pulley**
The main argumentation scheme in this case is ends and means (the pulley facilitate the process)
4.**They "see" the length of the rope**
Argumentation scheme: DH arguments that relate the more rope with the weight.

RESULTS

We have found that the tasks influence the type of argument-schemes by different ways. They depend on features of the task, as well as on the personal interpretation of student of this, related to the way we present the task, and sometimes also related to their misconceptions, intuitions or personal or common experience. Among others, we have found several features influencing the argumentation of the students in specific ways such as:

- The proposed problem contains given arguments that can favour their use in the argumentation of the students. (Case of the snowman task 3)
- The problem offers a situation about which students have to take the most convenient decision related to a possible physical action that they could carry on. This type of problem can foster types of argument schemes by consequences or linked to an anthropocentric focus, e.g. personal physical feelings. (Case of the task 3 and task 4)
- The problem has a statement that allows a geometric point of view (a drawing as in our example), arguments are strengthened with geometric assumptions that foster some specific schemes or premises (e.g. can use the premise that the weight depends on the distance with the ground). (Case of the task 1)
- The situation of the problem presents an object that is considered to have a specific functionality (e.g. the function of a coat), the task can be viewed and argued from the standpoint of this functionality (as we have seen in the example of heat transfer with the snowman covered with a coat)
- The possible relationship of the proposed tasks to any science law or theory studied in school or in the textbooks that brings to the student's application of that law or theory to interpret the situation of the task. (Case of task 1).
- The possible relationship of the proposed tasks to any scholar o from the media experiment and the interpretation that student give of that experiment. (Case of task 1and 2)

In summary, our results have shown us that the more points of view that can be adopted by our task, the larger the variety of arguments can be given by students. This is always linked to the knowledge of the student, either established by science (e.g., gravity/distance to the centre of the Earth) or intuitively (e.g., the boy feels stronger). These last types of tasks will be the most appropriate if the teacher wants to teach in a class with dialogical discussion.

CONCLUSIONS AND IMPLICATIONS

From this and earlier studies, we are improving our understanding of students' arguments in relation to science conceptions. For science education the result from our research about the interrelationship between the four elements identified by means of the analysis (features of the problems-tasks, previous scientific ideas students have, personal interpretation of the tasks' situations and the argumentative schemes used by the students performing the tasks in small group) is very relevant. As our research is limited, further studies are needed about argument schemes that students use in science classes to improve our comprehension of students' conceptions in science and also our knowledge of common sense argumentation. An implication of our research could be to include not only students' misconceptions in teachers' training programs but also the most common students' argumentative schemes for deeper understanding of their reasoning. This is important because the teachers will be able to use these argument schemes in their dialogical classes as a "tool" to favour the process of learning science and to provide "clues" to help them to choose appropriated activities in science education.

TEACHING SCIENCE IN THE MIDST OF FUZZY DISAGREEMENT: A STUDY OF ARGUMENTATION IN A CLASSROOM

Danusa Munford[1], Ana Paula Souto-Silva[1] and Diego Oliveira da Silva[1]
[1]Faculdade de Educação, Universidade Federal de Minas Gerais, Brazil

Abstract: In this study, in order to learn about a novice teacher's practices in argumentative contexts, we examined discursive interactions in a science classroom. We intend to contribute to research on *processes* involved in supporting science learning through argumentation. A naturalistic design utilizing qualitative research methods and interactional ethnography was employed to investigate two research questions : In what aspects argumentation differs in various instructional contexts of a science classroom?; How a science teacher uses language in different argumentative contexts in the classroom?. The main data sources were: participant observation conducted during 8 months, field notes, audio and video records of science lessons, 3 interviews with the teacher. Pragma-Diale ctical theory of argumentation was adopted to analyze data. The results show differences in argumentation among episodes from various instructional contexts in relation to: relationships among the differences of opinion; nature of the differences of opinion; structure of the argumentation; roles of participants; and whether argumentation components were made explicit or were implicit during discursive interactions. The teacher's language use varied in two aspects: how he raised questions and how he made explicit/implicit his points of view. Teacher's discursive strategies were influenced by his goals as well as relationships between students' knowledge and scientific school knowledge.

Keywords: Argumentation; argumentation theory; teaching practices; science learning

INTRODUCTION

Seeking to better understand how knowledge is socially constructed in classrooms, educational researc hers have turned to the study of discourse in school context. Some of the implications of this perspective are that language is perceived as mediational mean for thinking, and that the role of the teacher is of a "language user" who supports conceptual understanding (Edwards & Mercer, 1987). Researchers and policy makers consider argumentative discourse as essential in science learning (e.g., Driver, Newton, & Osborne, 2000; JiménezAleixandre & Erduran, 2007; NRC, 2000; Sadler, 2006; Sandoval & Milwood, 2007; Schwarz, 2009; Scott et al., 2007; Zohar, 2007). Nevethelless it was only relatively recently that the relationship between learning and argumentation became focus of research in science education (Andriessen , 2006; Baker, 2009; Chinn & Osborne, 2010; Schwarz, 2009). Moreover, although scholars acknowledge the significance of teaching when trying to understand learning, there are still few studies on aspects of teachers' practice in argumentative contexts and how they can impact learning (e.g., Avraamidou & Zembal-Saul (2005); McDonald, 2010; McNeil & Krajcik, 2008; Osborne, Erduran & Simon, 2004; Sandoval & Reiser, 2004; Venville & Dawson, 2009; Zembal-Saul (2008). Finally, frequently, the studies focus on the quality of arguments produced by students or teachers, not in *how* people argue to reach some agreement.

In this study, to learn about a novice teacher's practices in argumentative contexts, we examined discursive interactions in a science classroom. We intend to contribute to research on *processes* involved in supporting science learning through argumentation. We investigated the following research questions: 1) In what aspects argumentation differs in various instructional contexts of a science classroom?; 2) How a science teacher uses language in different argumentative contexts in the classroom?

METHODS

Research Setting

The study took place in a middle school science classroom for adult learners in a night shift school, which was part of an outreach university project. We acknowledge the existence of adult learners' particulatities, but we believe that some of these characteristics have parallels in children and teenagers(e.g., conflicts between everyday knowledge and scientific knowledge). Thus, studing adults can contribute to a better understanding of science learning in general – as has been argued for other non mainstream groups.

The teacher, Mr Sunday, had graduated very recently, but worked as teacher for about two years before data collection. He was very committed to promoting students' learning, and he was very attentive to learners' demands. Although he often teached through lectures, he interacted a lot with students, mainly due to his abilities in encouraging them to participate and in posing questions to check understanding.

Methodological Orientations

A naturalistic design utilizing qualitative research methods (Lincoln & Gubba, 1985) was employed in the present study. It can be characterized as a case study (Stake, 2000; Merriam, 1998), informed by interactional ethnography (Castanheira et al.,2001; Dixon & Green).

Many studies on argumentation in science education had used Toulmin's model as a methodological framework (Driver et al., 2000; Erduran, 2007), they usually have as focus the quality of the argument/argumentation and characteristics of their different components. In our study we chose to use the Pragma-Dialetical theory of argumentation (Van Eemeren *et al.*, 1996, 2002) to learn about *argumentation processes* in learning contexts. We focused on teacher's moves throughout argumentation, and the procedures involved in resolving differences of opinion, always considering the broader context in which argumentative interactions took place.

Data Collection

During eight months, the second author conducted participant observation (Spradley, 1980) with narrative recording in field notes, combined to audio and video recording (Green et al., 2001). Following a contrastive perspective (Castanheira et al., 2001), in this study, we focused on episodes from three lessons with different characteristics (see Table 1). We also conducted three two-hours long interviews with the teacher to have insights into participant's perspectives. Finally, we had access to teacher's written records about the lessons.

Table 1: Major characteristics of the lessons

	LESSON 1	LESSON 2	LESSON 3
Theme of the lesson	Blood types (ABO): antigens/ antibodies	Choosing units to measure solid waste	Ecological Relationships between living beings
Instructional context	Lesson is part of a series of lessons that address Circulatory System	Lesson is part of an inquiry unit on solid waste	Lesson is part of a series of lessons on ecological interactions.
	Lesson is conceived to prepare students for a Lab Activity	Lesson is conceived to prepare students for collecting data on their own waste	Lesson is conceived to prepare students for reading a book on Ecology and doing a group presentation.
Learning focused on	Scientific Concepts	Scientists Practices	Scientific Concepts
Differences of opinion involving…	Students' knowledge versus School Science knowledge	Teacher's and students doubts	Different points of view from School Science knowledge

Analyses

The first phase of analysis involved transforming audio and video records into some type of written or graphic representation of data (Cameron, 2001). We used tools from Interactional Ethnography such as event maps and story lines with different grain-size (Castanheira et al., 2001; Green & Dixon, 2005). Through this analysis it was possible to identify key-events involving argumentation related to learning scientific inquiry practices. A total of 7 episodes (each lasting from 5 to 20 minutes) were transcribed word-by-word.

Initially, the transcripts were analyzed having as major reference the "analytic overview" framework and evaluation procedures from Pragma-Dialectical theory of argumentation (Van Eemeren et al., 1996, 2002). This theory combines aspects of discourse analysis, rhetorics and dialectics to analyze argumentation. We focused on i) identifying points of views, and establishing what were the main and subordinate differences of opinion, and whether they were explicit or implicit; ii) identifying protagonist or antagonist positioning; iii) characterizing the structure of arguments. In addition, to better understand the context of interactions we went back to video records, field notes, interviews and teacher´s classroom records.

Moreover, based on Van Eemeren and colleagues' work, we developed three different types of representation to better visualize how arguments were constructed through interaction and how argumentation differs in the various contexts: i) representing relationships between argumentation components and discourse (Figure 1); ii) representing the whole structure of argumentation in detail at the end of the episodes, considering the multiple points of view at stake (Figure 2); iii) representing the whole structure of argumentation, but in a way that makes visible broader characteristics of argumentation in the episode (e.g., the relationships between main and subordinative differences of opinion) (Figure 3).

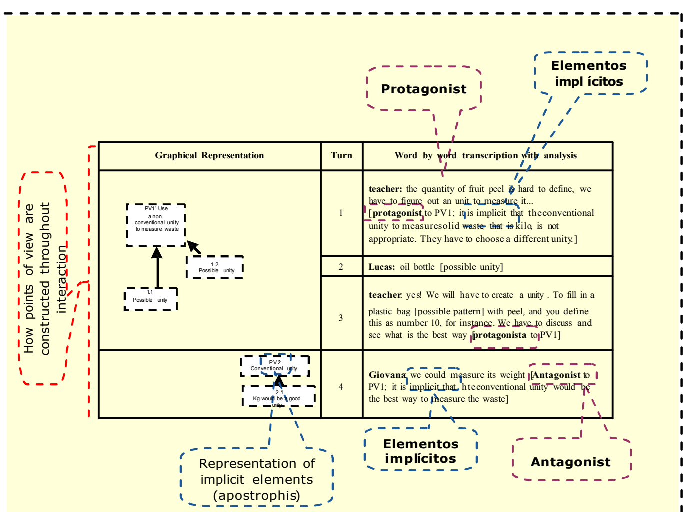

Figure 1: First type of representation created to use Pragma-Dialectics in classroom-based studies of argumentation. It is generated *during transcript analysis* with the goal to establish direct relationships between participants' talk and elements of argumentation (points of view and supporting elements) and how they are constructed through time.

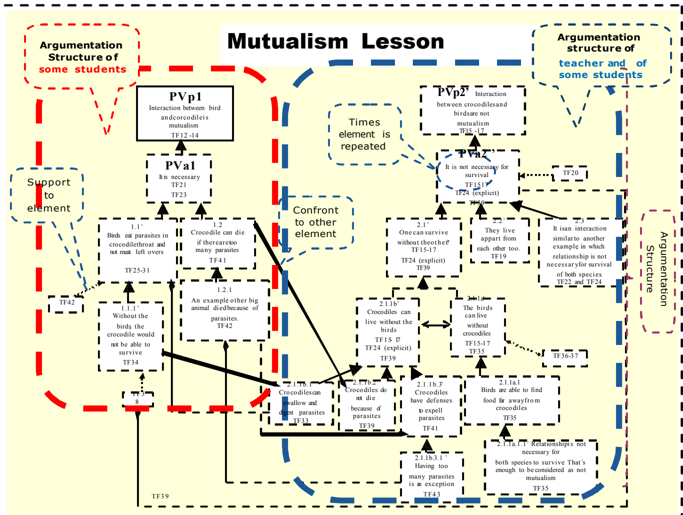

Figure 2: Second type of representation created to use Pragma-Dialectics in classroom-based studies of argumentation. It is a summary of results of transcript analysis. It makes it possible to identify points of view and supporting elements of argumentation, as well as provides evidence on how (and by who) arguments are generated in interaction.

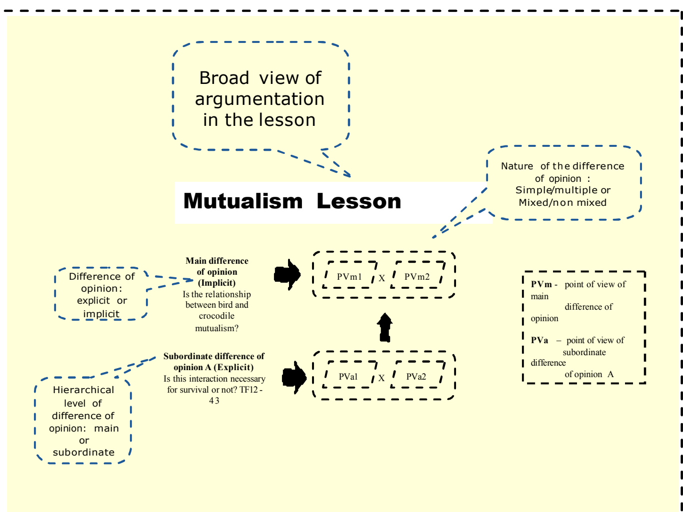

Figure 3: Third type of representation created to use Pragma-Dialectics in classroom-based studies of argumentation. This representation makes it possible to characterize the broad structure of Argumentation, that is, the hierarchical relationships between major difference of opinion and secondary differences of opinion.

Results

The results show differences in the nature of argumentation in the three lessons. In the “Blood Types” lesson we identified greater complexity in the *relationships between differences of opinion*. In this lesson, there was one main difference of opinion and two *levels* of subordinative differences of opinion. In each level, we identified two differences of opinion. In sum, the argumentation in lesson 1 involved complex hierarquical relationships among the various differences of opinion (Figure 4).

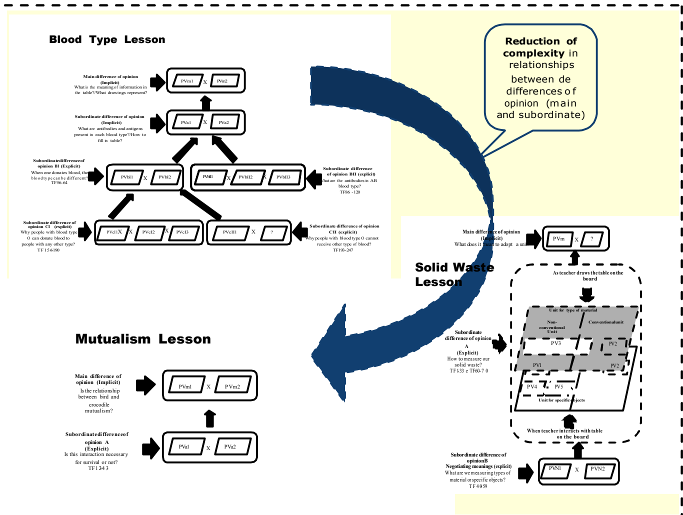

Figure 4: Representations of hierarquical relationships between various differences of opinion in the three lessons. The contrast shows that there is a greater complexity in these relationships in the Blood Type Lesson.

In the Solid Waste Investigation lesson we identified greater complexity in the *nature of the difference of opinion*. In the subordinative difference of opinion more than one proposition was under dispute *and* involved various points of view (Figure 5). Moreover, there was a process of reformulation of these points of view and search for conciliation between them. Maybe this complexity is related to the fact that the teacher was not sure about the answer to the problem posed.

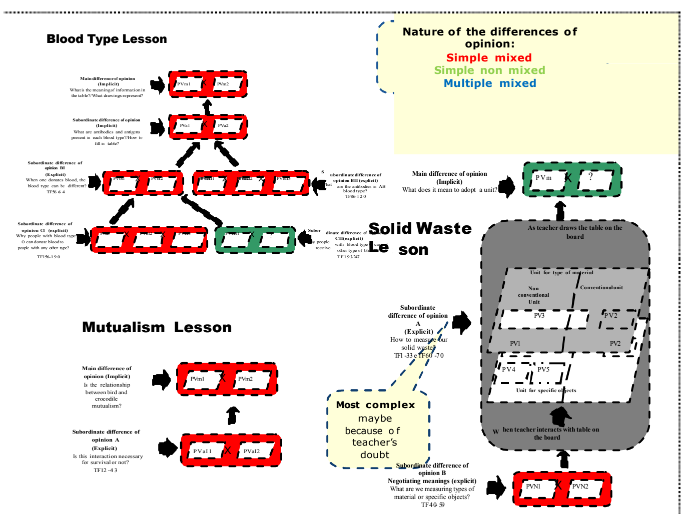

Figure 5: Nature of differences of opinion in the three lessons. The contrast shows that differences of opinion had a more complex structure in the Solid Waste Lesson, that is, in a inquiry based unit when the teacher was not sure about how to answer the problem that was posed.

Finally, in the "Ecology" lesson, we identified greater complexity in the *argumentation structure*. In this case, Mr. Sunday´s argumentation was multiple, subordinative and coordinative (see Figures 6 and 7 for a contrast between the three lessons).

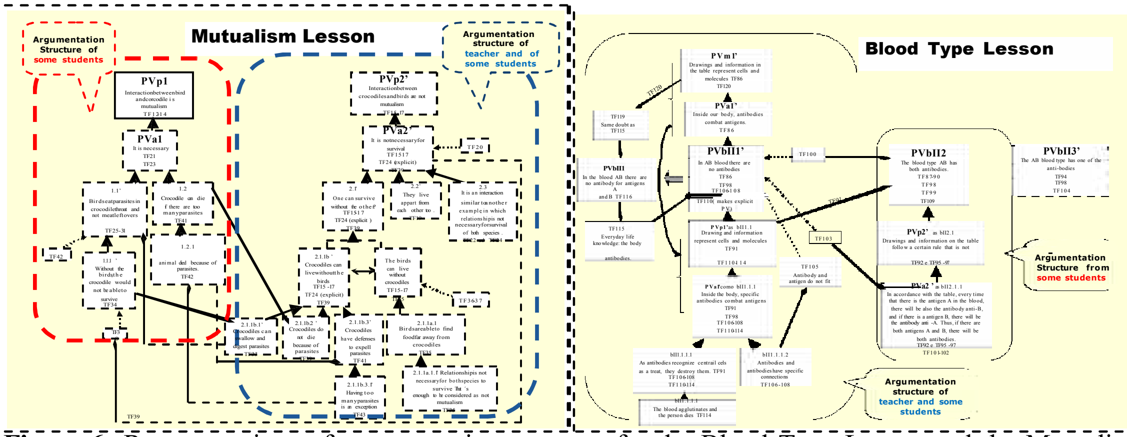

Figure 6: Representations of argumentation structure for the Blood Type Lesson and the Mutualism Lesson. The contrast between these two lesson shows difference in the structure of students' argument, which is more complex when they share scientific ways of reasoning and have greater domain of subject matter knowledge.

In all the three lessons, Mr Sunday tended to act both as protagonist of his own point of view and as antagonist of others' point of view. An exception is in lesson 2, when he had doubts about what was the best unit to be used to measure organic solid waste. In this case, he defended multiple points of view, acting as protagonist and antagonist of them. The students, on the other hand, tended to act only as protagonists of their points of view.

The premisses involving the differences of opinion (main and subordinative) in lessons 1 and 3 are, in general, implicit. Only in lesson 3 the main difference of opinion is explicit, making it possible, for the participantes to be conscious of what is issue leading to desagreement.

We idenfied a significant variation in Mr. Sunday's language use in two aspects: how he raised questions and how he made explicit/implicit his points of view or his arguments. Our analisys indicated that teacher's discursive strategies were influenced by the goals of the teacher, as well as the relationships between students' knowledge and scientific school knowledge. Another interesting aspect of Mr. Sunday's practice was that, through language and with a single uterance, he simultaneously kept discussion open and oriented discussion to a closure.

Implications and Conclusions

Our study supports the notion that argumentation occurs in science classrooms in different forms depending on the context and certain aspects seem to be particularly influential. It also indicates that teachers can develop strategies to teach science in argumentative contexts, using language in various forms. Finally, this researchalso makes evident that the field of Theory of Argumentation can contribute to the development of new methods to investigate argumentation and science learning.

Abstract: The purpose of this case study was to describe what kinds of classroom discourse types transfer teachers used and any variations in discourse types when teaching an interaction diagram and N3 law. A further aim of this study was to ascertain whether there was any relation between the variation in classroom discourse types and student learning outcomes for the interaction diagram and N3 law. The teaching sequence in the context of force and Newton's third law was designed and implemented by three transfer teachers (teachers who had not participated in designing the teaching sequence) in three Finnish upper secondary schools. The lessons were video-taped and the most important episodes of the lessons were transcribed. Student learning was monitored with a pre-test and three post-tests**.** The discourse types, duration of discourse types, and the content and purpose of topics in the selected episodes were analysed with a visual tool specifically developed for this purpose. Our main findings suggest that the familiarity of the teachers with the content may influence the variation of discourse types. The results also provide some evidence that variation of classroom discourse types may also support students' learning. The findings of this study have implications for teacher education and education research with the introduction of a visual tool developed for analysing classroom discourse.

Keywords: Classroom discourse, interaction diagram, Newton's third law, learning, transfer teacher

INTRODUCTION

Many studies, especially over the last decade, have furthered understanding in the role of discourse in science teaching and the different characterizations of classroom discourse (e.g. Furtak & Shavelson, 2009; Mortimer & Scott, 2003; Scott, Mortimer & Aguiar, 2006; Viiri & Saari, 2006). As different classroom discourse types serve different purposes, any teaching sequence should include a variety of discourse types (Mortimer & Scott, 2003; Scott et al., 2006). According to Mortimer and Machado (2000), the variation of the discourse type between authoritative and dialogic discussion is dependent upon the teaching purpose and aims, with different types of discussion being used accordingly. The study of Furtak and Shavelson (2009) gives some empirical support that the variation of discourse types builds students' conceptual change: teachers of students with higher learning gains were more likely to vary the kind of guidance (authoritative or dialogic) they provide for students than the teachers of students with lower learning gains. According to Scott (2008), the appropriate discourse types developed by the teacher have the potential to motivate students and to draw them into the science contents. This brings about a need for a pedagogy which is based on purposeful shifts in discourse types as well as a need to develop methods to study these shifts.

In this case study we are interested in the types and the variation of types of classroom discourse in the teaching of an interaction diagram (ID) and Newton's third law (N3 law). This study is part of a wider study that is investigating the use of an ID and how it supports the learning of concept of force in the case of transfer teachers; by this we mean teachers who implement the teaching sequence but are not involved in designing the sequence or lesson materials. The use of transfer teachers offers an opportunity to study classroom discourse in normal school settings; there are not many studies involving transfer teachers (Leach & Scott, 2002).

Interaction diagram is a symbolic representation of interactions where the components of contact and distance interactions are visually identified (Fig 1). The common view among students is that forces are understood as properties of objects. The ID provides a tool to identify and represent interactions between objects, and thus helps students to perceive forces as the property of an interaction instead of a property of an object. There are evidence from studies conducted by Savinainen, Scott & Viiri (2005) and Hinrichs (2005) that the use of an ID enhances student understanding of the force concept. In this study we use the ID presented by Hatakka, Saari, Sirviö, Viiri & Yrjänäinen (2004) as it includes writing down the interactions in terms of pushing and pulling, and is also used in the physics textbook used in the teaching intervention of this study.

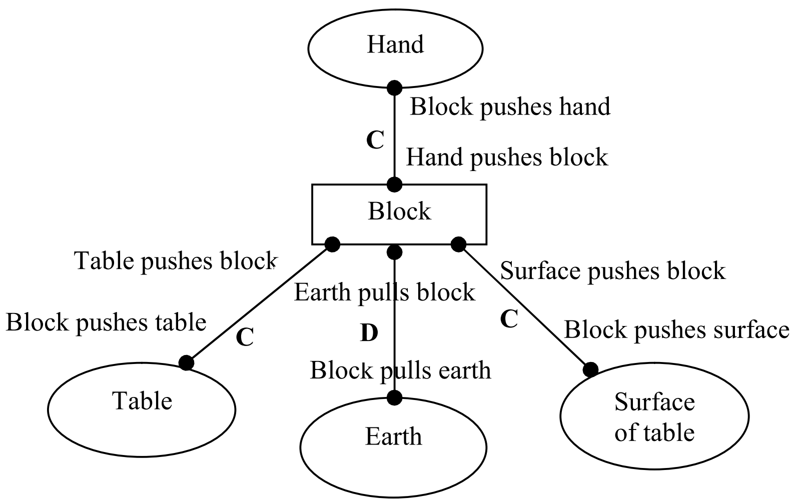

Figure 1. An example of an interaction diagram in the case of a hand pushing a block on the surface of a table. C = contact interaction and D = distance interaction.

PURPOSE OF THE STUDY

The purpose of this study is to 1) describe what kinds of classroom discourse types transfer teachers used and whether there was any variation in the discourse types in teaching the ID and N3 law, and 2) to find out if there is any relation between the variation of classroom discourse types and learning outcomes for the ID and N3 law.

Here the classroom discourse in physics teaching is examined by taking account of the purpose and context of teaching and students' learning of the content. In this study the research methods are developed in a way that the relationship between time, variation of classroom discourse types, purpose of teaching and students' learning can be expressed.

METHODS

This study is part of a wider study where an instructional teaching sequence in the context of force and Newton's laws was designed and evaluated. The teaching sequence (designed for 5 lessons of 45 minutes) was implemented by three transfer teachers in three Finnish upper secondary schools and was included in the introductory physics course that is compulsory for all upper secondary school students. In the introductory course the concept of force is taught for the first time in upper secondary school. The schools participating in the study were named T1 (25 students), T2 (27 students) and T3 (23 students). The lesson material designed for the teachers included teaching contents, timetable, examples, exercises, demonstrations and homework. All three teachers also followed the contents of the same physics textbook (Hatakka et al, 2004). The lesson material and the textbook supported each other by introducing forces as interactions and by using IDs. A more detailed description of the lessons is available in Savinainen, Mäkynen, Nieminen & Viiri (2011).

For the classroom discourse analysis, the primary data source was video-recorded lessons. Some important episodes were also transcribed in order to make the purpose of teaching more evident. The video material was analysed by using the Atlas.ti and Excel softwares. The episodes chosen for detailed analysis included the teaching of the ID and N3 law for the first time. These contents were also dealt with in other parts of the lessons, but teaching was mostly dealing with written tasks (the same tasks in all three schools), and the variation of discourse types in dealing with these tasks was about the same in all schools.

To make the purpose and variation of classroom discourse more evident, the discourse types, duration of discourse types, and the content and purpose of topics in the selected teaching episodes were analysed using a visual tool developed for this purpose (see Fig 3 later in this paper). The classification of the classroom discourse types followed the method of Viiri and Saari (2006), expanded by the sixth category called student's initiative (Nurkka, 2006). In the classification method the classroom discourse types are divided into six categories: teacher presentation (TP), teacher-guided authoritative discussion (AD), teacher-guided dialogic discussion (DD), peer discussion (PD), student initiative (SI) and other (O).

Students' learning were monitored by using a pre-test (FCI, Halloun, Hake, Mosca & Hestenes, 1995) with four multiple choice questions addressing Newton's third law and by three post-tests. The post-tests were given 1) after teaching the ID and N3 law, 2) at the end of the teaching sequence, and 3) two weeks after the teaching sequence. The post-tests included constructing IDs in various physical situations (altogether eight diagrams in three tests) and four questions on N3 law (two multiple choice questions and one question of force pairs in interactions in test 2 and one multiple choice question framed in a vectorial representation with a written justification in test 3). All the questions were derived from research-based materials. The interaction diagrams constructed by students were categorized according to three quality categories (Table 1).

Table 1. The classification of the quality of IDs constructed by students.

Excellent	Good	Poor
All interacting objects identified.	All interacting objects identified.	At least one interaction is missing or an extra interaction is included.
Interaction line or arrow presented.	Interaction line or arrow presented.	*or* Instead of interactions, forces are identified
Type of interaction (contact or distance) identified *or* a verbal explanation of interactions presented.	Neither type of interaction *nor* verbal expression of the interaction in presented.	*or* Diagram lacks essential features of interaction diagram.

RESULTS

The classroom discourse types the teachers used in episodes of teaching the ID and N3 law varied between the schools and also in teaching content (Fig 2). In each school the classroom discourse type used to teach the ID was predominantly teacher presentation. In school T1 there was more variation in classroom discourse types during this episode than in schools T2 and T3. In the N3 law teaching episodes, schools T1 and T3 used more variation in discourse types than in the ID teaching episode with more dialogic discourse employed.

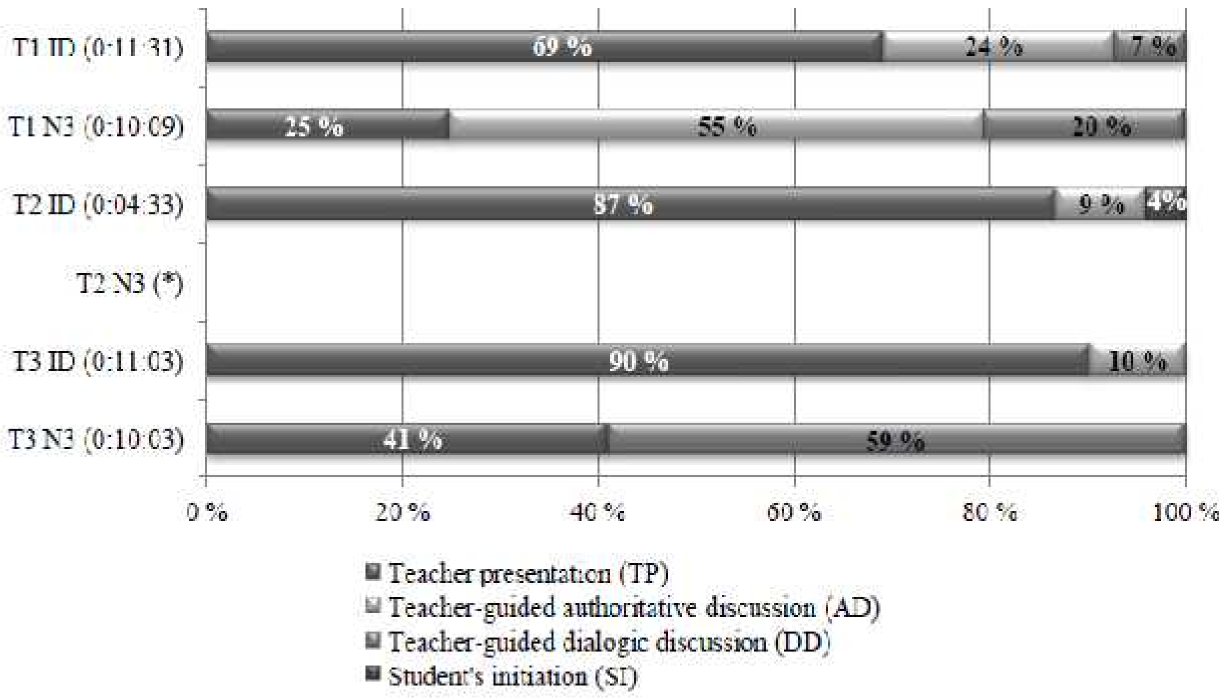

Figure 2. The percentage of classroom discourse types (counted from the duration of episode) during the first teaching episode of ID and N3 law in schools T1, T2 and T3. The total duration of the teaching episode is presented in parentheses. *) The video-recording was not successful.

In school T1 there were more shifts between different discourse types than in the other schools where periods of certain classroom discourse types were longer. As an example of the variation of discourse types, an analysis of the rhythm of the classroom discourse and the purpose of teaching in the school T1 during the episode of teaching of ID is presented (Fig 3). This kind of analysis reveals how the teacher uses different variation of classroom discourse types for different purposes.

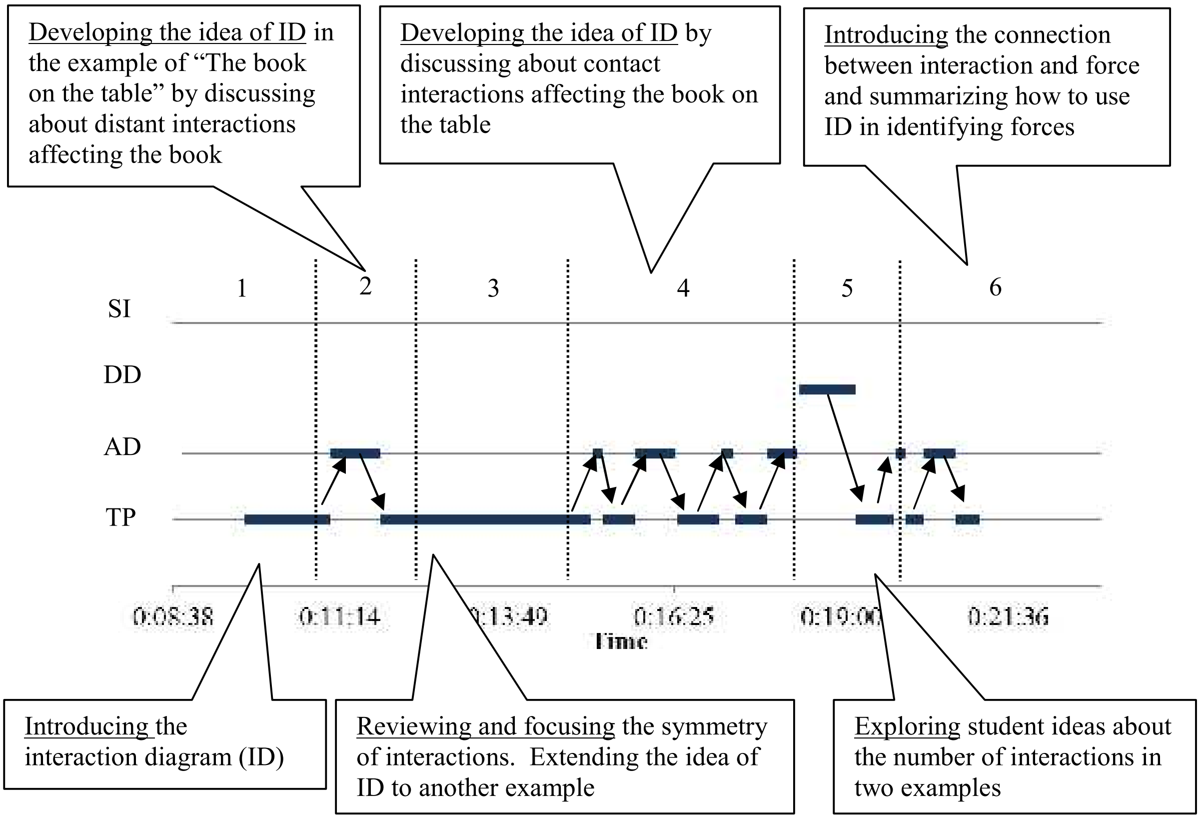

Figure 3. Types of classroom discourse, duration of discourse types, and the content and purpose of topics (1 – 6) in school T1 during the first teaching episode of interaction diagram. TP = teacher presentation, AD = teacher-guided authoritative discussion, DD = teacher-guided dialogic discussion, SI = student's initiation.

The interaction diagrams the students constructed were categorized according to three quality categories (Table 2). In school T1 there were more IDs in category "Excellent" than in schools T2 and T3. Differences between schools T1, T2 and T3 in students' learning of ID were statistically significant as measured by the relative frequencies of different quality categories of IDs ($\chi^2 = 230.3$, df = 4, $p < 0.001$).

Table 2. The distribution of interaction diagrams according to different quality categories (Table 1) in schools T1, T2 and T3. N indicates the total number of IDs included in the percentages below (altogether 8 diagrams in three tests). Students absent from the test or non-answers for the task were not counted.

	Excellent	**Good**	**Poor**	**Non-answers (Number of IDs)**
T1(N = 192)	85%	1%	14%	8
T2 (N = 210)	18%	59%	23%	6
T3 (N = 167)	71%	17%	13%	17

Students' learning results for the N3 law are presented in Table 3. Maximum score for N3 law questions altogether in three post-tests was 4. In counting the learning results only the students who were present in all tests (pre-test and three post-tests) were included. If the student did not answer the question, the answer was interpreted as wrong. There were no significant differences in pre-test results, but in post-tests, the best learning results were in school T1. For the post-test questions the differences were statistically significant between schools T1 and T2 (Mann-Whitney *U*-test: z=2.59, p =.010) and between schools T2 and T3 (z=2.08, p=.038)

Table 3. Learning results of Newton's third law (counted as average percentages of maximum score 4). Standard errors of mean are presented in parentheses.

School	Four pre-FCI N3 questions (%)	Four post-test N3 questions (%)
T1 (N = 23)	28 (5.7)	83 (3.4)
T2 (N = 25)	26 (6.2)	64 (5.6)
T3 (N = 20)	28 (5.7)	80 (4.7)

CONCLUSIONS AND IMPLICATIONS

In teaching N3 law, teachers used classroom discourse types more diversely and they also used more teacher-guided dialogic discussion than teaching interaction diagrams. In teaching IDs teachers mostly used teacher presentation. Interaction diagrams were not very familiar to the transfer teachers before the teaching intervention, whereas N3 law was very familiar to all the teachers. Hence, our results suggest that teacher familiarity with the teaching content may influence the variation of discourse types. The more familiar the teaching content is to the teacher, the more diversely the teacher is able to use different classroom discourse types.

The variation of different discourse types was different in schools T1, T2 and T3. In school T1 the teacher varied the classroom discourse types more often than in other schools and used different discourse types for different purposes, for example, teacher-guided dialogic discussion to explore students' ideas, teacher-guided authoritative discussion to develop the idea of the content, and teacher presentation to introduce the new idea or summarise or focus the key points. In schools T2 and T3 even if the teacher used different types of classroom discourse in teaching N3 law, the periods of certain classroom discourse types were longer and the teachers did not vary the types of classroom discourse clearly according to the purpose of teaching. Even if parts of the video-recording done in school T2 were not successful, other video-data from school T2 indicates that the teacher did not greatly vary classroom discourse types, and in fact used mostly teacher presentation.

Our results provide some evidence that variation of classroom discourse types may support students' learning as reported by Furtak and Shavelson (2009). The best results in the learning of interaction diagram and N3 law were in school T1. In school T1 there was also more variation in classroom discourse types than in the other schools.

In this study we developed a visual tool for the time-based analysis of the classroom discourse. The tool was developed especially to express the relationship between time, variation of classroom discourse types, and purpose of teaching. The visual tool gives the possibility to analyse, reflect upon and modify classroom discourse by taking account of the content and purpose of teaching. Thus we consider the visual tool to be beneficial for teacher education, education researchers, and teachers. In further studies the tool might be developed to be more useful in exploring how the variation of classroom discourse types supports students' conceptual understanding.

MAKING MEANING OF GRAPHICAL REPRESENTATIONS IN BEGINNERS' PHYSICS LESSONS

Gesche Pospiech[1] and Ulrike Böhm[2] and Marie Geyer[1]
[1]Faculty of Sciences, Department of Physics, TU Dresden, Germany
[2]Centre for Teacher Education and Education Research, TU Dresden, Germany

Abstract: Mathematics and physics are characterized through a subtle interplay, not only in science itself but also in physics education. Significant problems arise when students have to connect the different perspectives of these subjects and to use different mathematical and physical representational elements. These abstract objects have to be introduced to the students carefully with aid of verbal explanations in order to clarify this interplay. We describe possible obstacles during this process with an example from beginning physics lessons concerning the steps starting from describing an experiment, its evaluation by verbal circumscription and by graphical and mathematical tools. To obtain a complete picture we first analysed text books. On the basis of the qualitative understanding of pupils and teacher students a questionnaire was developed which highlights possible misunderstandings.

Keywords:

Introduction

Teaching beginners in physics is an exceptional important and responsible task. Introducing pupils to the idealizations of physics and physics models starting from everyday experiences and interpretations requires careful designing of a learning path and choosing an appropriate language. Students do not come ignorant into physics lessons but have knowledge from own observations and from other lessons e.g. in mathematics. Also the teacher has his or her own experiences and is already socialized in physical thinking. Those two different starting points have to be matched. This concerns understanding of fundamental physics concepts as well as simple descriptions and explanations. We will present here an example of possible misunderstandings on the border of mathematics and physics which needs careful attention as critical details might influence the physics course as a whole. Especially tacit assumptions have to be made clear to the students, because between real observations and the description by physical terms and abstract models lies a wide gap whose difficulties often are underestimated, (Böhm et al. 2010). In bridging the gap language serves as a medium for the meanings of symbols, notations etc and hence also plays a central role.

The idealization process in physics is strongly related to the use of physical models as well as of mathematical elements. The interplay of empirical, conceptual and mathematical elements in doing physics is most subtle and shall not be discussed here in detail, (but see e.g. Kuhn (1976), Wigner (1960), Gingras (2001)). The use of mathematical elements on different levels characterizes the physical method and is part of the way of gaining knowledge in physics. Hence, understanding the meaning of mathematical tools for the physical description of the world and their interplay with physical views is one of the most important, but also most difficult steps in physics education. Students have to learn to represent physical relations by mathematical symbols and vice versa. This already starts with the very first experiments where quantities are being compared or measuring values are taken and represented graphically. Students have early experiences in this from mathematics lessons. But there are subtle differences between the teaching in mathematics and physics, caused by their different perspectives. In physics, numbers and the view of graphs have to be interpreted in terms of physics laws which are by themselves only approximations to real processes.

Pupils have to cope with these differences, (Redish, 2005; Pospiech, 2006). The flexible use of representations is a central ability which marks the experts in comparison to novices, (Friege, 2001). Among them the handling of graphical representation takes an eminent role as it is important also for other sciences than physics, (see e.g. Ainsworth (1999), Lachmayer et al. (2007)). Especially the interplay of the representation forms: verbal explanation, diagrams and formula is important for the process of learning and understanding. It contributes to the forming of pupils’ mental models. However, the implicit meaning attributed to verbal descriptions may differ between teachers and their pupils according to their experience. Therefore a common base of understanding has to be developed over time. In order to gain an insight into this process we concentrate on the connection of different mathematical elements with a physical experiment and the mediating language and study the process of making meaning as it is performed by students.

Bridging different representations

The first mathematical elements mostly enter physics lessons in the course of an experiment with taking data, preparing a table of measured values and drawing a suitable diagram. Accordingly, by the term "mathematics in physics" we do not only understand formulas, i.e. the algebraic representation, but also graphical representations. Graphs are an important tool for depicting experimental data and evaluating them whereas formulas are a very condensed way of describing a physical relationship in a precise manner. Generally, they do not have the ambiguity of verbal explanations.

During the learning process a kind of a grammar and vocabulary for the translation process between these representations has to be established. These first steps seem to be simple, but they are the basis for subsequent development of physical thinking and the mastering of methods in physics inquiry. However, beginners have difficulties to grasp the relation between a formula or function and the related graphs. Therefore, formulas and diagrams require verbal explanations which are essential in connecting the different representations. From this point of view the step from phenomenon to the mathematical formulation is gone too fast in the eyes of pupils, (Monk, 1994). Therefore the connection of physical quantities and mathematical tools has to be developed carefully, (Pospiech, 2007). The prerequisite for developing a suitable learning environment is the exact knowledge of possible difficulties pupils encounter. As a first step towards this we conducted a descriptive study with a focus on the interplay of making and interpreting graphs and its verbal description. The central question was: “How is the verbal description set in relation to a graphical representation?”

In beginners' lessons the language has to rely highly on everyday language as the specialized language is not yet at disposal. The everyday language has in general a broader meaning than the specialist language. It lives from associations which can differ between students and teachers, (Pospiech, 2009). Therefore a negotiation process between the parties has to take place. Experienced teachers systematically use key words for this purpose. Often students learn by experience which words to use to denote physical or mathematical relations. Since spontaneous associations together with influences from mathematics lessons are especially important in beginning lessons we choose an example from grade 6 (students aged 11 to 12 years). The research focus lies on whether teacher students and pupils have the same physical or mathematical interpretation of the linguistic terms.

Learning Context

The study on the role of linguistic elements was conducted at an example from introductory thermodynamics. It combines a concrete experiment done by pupils, its verbal description, graphical representation and a mathematical tool, the proportionality or linear function.

The physical context is the thermal behaviour of bodies and the concept of temperature. As it is the beginning of physics instruction the pupils are introduced to the techniques of experimentation. An easy experiment consists in heating a certain amount of water with an immersion heater and observing the increase of temperature. It is an experiment prescribed in the curriculum, by which the pupils learn how to set up and conduct an experiment, make a protocol and so on, mostly from the technical and methodological perspective. This experiment includes several steps: during the experiment the pupils take the time, read the corresponding values of temperature and write them down in a table. After that they are asked to draw the suitable diagram and to interpret it.

In the context of thermal energy the same topic is treated again in grade 8 (13 to 14 years old) with the inclusion of melting and boiling and with the objective of deriving or making plausible the heat equation $Q = c_W \cdot m \cdot \Delta T$.

Therefore we choose this subject from thermodynamics for deeper analysis. The aim is to analyse how the pupils put together different representations and how (future) teachers understand all the terms used in school books, in mathematics lessons and everyday understanding.

METHODS

In a first step we analysed physics text books for schools with respect to their description of the process of heating water and mathematics books concerning definition and use of the term "proportionality".

In the second step students were observed and assessed after doing the experiment "heating water" and its evaluation. From this pilot study a questionnaire for students and teacher students was developed, in order to get a detailed view on possible discrepancies between their use and understanding of language.

Analysis of Schoolbooks

Especially the physics books for grade 6 do not give a precise mathematical description, but circumscribe the process by words. Some of them use the wording: “The temperature increases steadily.” This rises the question, whether pupils connect to the term "steady increase" the correct physical understanding and an adequate graphical representation. In books of grade 8 the corresponding explanation reads:

> “Supplied energy and temperature increase are proportional if no change of state takes place."

> “The heat Q supplied to an object is proportional to the temperature increase ΔT: $Q \sim \Delta T$.”

In the books, diagrams are just given without further comment such that the teacher has to explain their making and interpretation. Mostly the diagrams depict an idealized curve, only in some schoolbooks measuring values are indicated. Measuring values corresponding to the chosen example always lie on a straight line. Only some books refer to measuring errors. So pupils mostly get an idealized image of the relation of real measuring values and their representation.

The mathematics books of grade 6 introduce the concept of “proportionality”, mostly with the meaning: “direct proportionality”, sometimes also the “indirect proportionality”. Therefore the pupils are used to a strict mathematically correct definition of “direct proportionality”, where the corresponding line has to go through the origin of the coordinate system. In grade 8 the most prominent example for a function is the linear function. In contrast to the strict use in mathematics physicists describe arbitrary physical relations between two quantities often with the term “proportional”, as e.g. “Force of gravity is proportional to $1/r^2$”

Exploratory Study and Questionnaire

In the exploratory study the teacher performed in the normal course about thermodynamics the experiment "heating water" with the description in terms of a "steady process". Then the students (n=25, 15 male, 10 female) were asked to describe the results of the experiment (values and graphical representation) by their own words in order to know what they understood by the term “steady process”. These descriptions were evaluated with respect to the used mathematical and physical arguments. A second perspective was introduced by interviewing different people - physicists, becoming teachers, non-physicists - on this topic.

From the answers of both groups we derived possible understandings of the term “steady process” and condensed them into 12 items, e.g. “There are no sudden changes.” or “Something proceeds at constant speed.”, “It is a regular process”. Fitting to these "definitions" we chose 10 graphs, about which we asked pupils and students whether or not they would relate them to a “steady process”. Examples of the graphs included e.g. periodic functions, non-linear graphs and increasing as well as decreasing straight lines. These both aspects - the linguistic as well as the graphical - were combined in a questionnaire.

The questionnaire was given to 63 pupils from two classes (22 male and 41 female pupils) of grade 6 (about age 12) and to 14 physics students (shortly before end of their study). In addition a similar task was given to 63 students of grade 8 (about age 14, 32 male and 31 female). They should assign given graphs to the description: “A physical quantity *M* changes steadily with a physical quantity *L*.”

RESULTS

Exploratory study

The verbal explanations of the students in the pilot study showed that they attributed a “steady increase” only if the measured values lied strictly on a straight line. If there were even small deviations, e.g. by measuring errors, they mostly rejected the steady increase. Furthermore some denied the direct proportionality because the line did not go through the origin of the coordinate system.

The explanations of the students show their attempts of sense-making. There is a tension between the exact description of their own diagrams from the evaluation of the experiment and the ideal images in the schoolbook together with the explanation of the teacher: “*The temperature rises always, but the higher the water is heated up the slower the temperature* *rises. Temperature → rises steadily.”*. Furthermore they try to deal with measuring errors and the perception of what might be correct: “*Temperature should increase steadily, but we make errors and that’s why they do not lie on a straight line. The points in a diagram ought to lie on a straight line.”* Furthermore, the difference between a dependent and an independent variable remains unclear: “*If time increases, also temperature increases. The temperature does not increase steadily, but the time does. Even if time increases steadily the temperature does not increase steadily.”* However, some students seem to adopt the idealization: “*The measuring values lie on a straight line, this means that the temperature increases steadily.”* Some pupils draw a connection to the mathematics lessons: “*The longer the time the higher the temperature. All points should lie on a straight line. This means the temperature rises always equally, but there is no direct proportionality. The temperature increases equally in every minute.”* That this student negates the direct proportionality can be attributed to the fact that in mathematics a direct proportionality always is shown by a straight line through the origin. But not all students transfer this definition equally strict: “*Since the points lie on a line and the time intervals are regular, they are directly proportional to each other and the temperature increases steadily.”*

Concerning the connection of process and graphical representation 16 out of 25 students made an explicit relation between the physical process, the steady temperature increase and its depiction in the graph. Only 11 students mention measuring errors and their influence on the graphical representation.

Results of Questionnaire

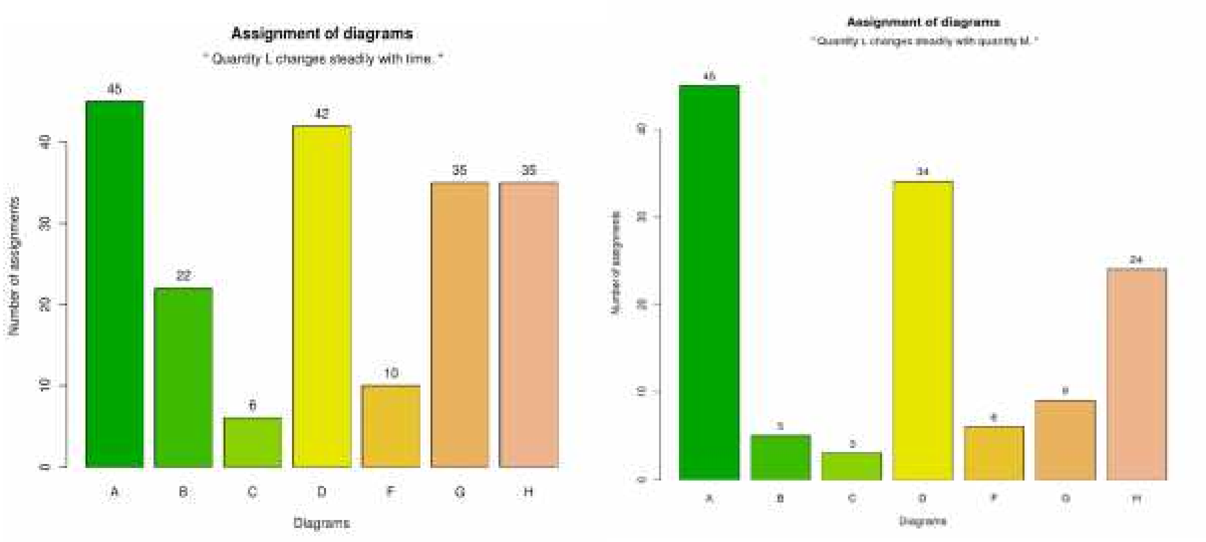
The questionnaire contained 12 alternative expressions for description of “steady process”. One of these had to be excluded because the students (grade 6) did not understand its meaning. Furthermore 10 graphs should be assigned to the sentence: “The quantity changes steadily with time.”.

Most items of the alternative descriptions for "steady process" were answered with a clear rejection or agreement. Especially the statement: “Something happens regularly” as a paraphrase for “steady increase” was agreed to by the students (yes: 71%). Also they agreed to “Something proceeds at constant speed.” (yes: 75%) or “There are no sudden changes” (yes: 76%). Students rejected a steady process if small or slow variations were allowed (no: 75% or 76% respectively). This implies that only smooth lines in diagrams would be identified with a steady process.

Interesting are the differences between students and physics teacher students. For instance the teacher students reject the paraphrase “Something happens regularly” clearly (no: 71%). Concerning the description “Something proceeds at constant speed.” teacher students were undecided, (yes 50%, no: 42%).

Concerning the graphs there is more agreement between the groups of students and teacher students. It is remarkable that increasing straight lines were quite surely accepted by most pupils (yes: 71% resp. 67%) as a depiction of a steady process, but a decreasing line to a lesser extent (yes: 56%)). More precisely, 61% of the students identify a process with constant speed with an increasing straight line, but only 47% with a decreasing straight line. They recognize that both graphs depict similar processes. In this last case there was the biggest difference between the attribution of students and teacher students, all of which connected the decreasing straight line to a steady process. A constant line was accepted by 79% of students as a steady process but only by 56% of the pupils. These differences can easily be explained by the far bigger experiences of students with mathematical functions. In the judgement of the "curved" lines students and teacher students mostly showed quite strong agreement in their classification.

Fig 1: In the diagrams the connection between graphs and the indicated text is given. The left refers to grade 6 the right to grade 8. Straight line graphs are A,D,G,H, where G is the constant function. B,C,F depict non-linear functions.



The question is whether the situation needs an intervention. The results of the questionnaire in grade 8 indicate that the students have reached a narrower understanding of the wording "steady process" and that teachers and pupils have reached a common adequate view (see Figure 1). The experience and negotiation of terms has led - without special intervention - to a quite satisfactory result.

DISCUSSION AND CONCLUSION

Misunderstandings or misinterpretations in beginners physics course can easily appear even at seemingly simple points. Especially interference with views from mathematics lessons where mathematical elements are defined very exactly has to be taken into account in physics lessons. Additional differences occur between the understanding of teacher students and pupils because an experiment, its evaluation or the underlying process are described and explained mainly with words. Those can be quite important for teaching,

This study shows that teachers have to be aware of differences in the attribution of meaning between themselves and their pupils. We see from the results that mathematical elements could - compared to verbal descriptions - secure a more stable accordance between the meanings of pupils and teacher students. Some additional aspects arose: pupils are very strict with respect to small deviances as they happen e.g. with measurement errors. They fall back on ideal standard representations. Therefore in teacher education it is important to show the teachers how to vary the representations, incorporate the possibilities of measurement errors and make clear the idealization process that is necessary for a mathematical treatment.

Abstract: A qualitative study based in the analysis of physics explanations in the university classes is presented. The aims is to analyze how the physic lecturer bulding their explanation identifying the multimodal resources and its function in the process scientific meaning building. The topic is Electromagnetism, specifically electric flux. The theoretical frame is structured on the Argumentation Theory by Perelman. The experience is carried out in Engineering School at Carabobo University, Venezuela. The dscourse analysis of three physics lecturers is made from multimodal perspective which takes into account the role of visual representation through action. The results contribute to three aspects: the lecturer resources used when looking for student's adhesion to the explanation, the communicative modes and functions in scientific meaning buldng and the interactive communicative process developed during the physics classes. This work is an advance of a bigger study that proposes to deep on the multimodal action of the lecturer in the meaning building for the development of three-dimensional vision of physics concepts and in general in the thinking of the engineering students, basic competence in the engineering profession.

Keywords: Discourse Analysis, *Rhetoric, Physics Teaching,* Engineering Degree, Science Education.

1. INTRODUCTION

This research is carried out in the Engineering Faculty at Carabobo University in Venezuela The main research aim is to identify rhetorical characteristics in the explanations of physic lecturer in an Engineering faculty through of discourse analysis of lecturers' classes. This aim will be concretise as: a) the description of the scientific meaning building of physics -through of lecturer's teaching analysis in the classroom and from a multimodal rhetoric perspective, that means, considering the convincing potentiality of the multimodal discourse of the lecturer; b) the analyze of how the physics lecturer builds the explanation about the electric flux concept, c) the analysis of the functions the lecturer gives to the multimodal resources he/she uses in his/her classes about electrical flux.

2. THEORETICAL FRAMEWORK

Science explanation analysis

We perceive the educational context from of Vigotsky Socio-cultural theory, where the appropriation of knowledge is caused by social interaction, which can happen in the classroom setting. The teaching learning process is based in the meanings building process lecturers carried out during their classes. We define *the Class* likes a string of speeches developed in a delimited situation in time and place, usually built over several days; in our case, which is guided by an experienced person to a less experienced people with a didactical purpose. Researches carried out about teachers reveal that self reflective practice on their work is a fundamental resource for the lecturers' training in that it involves rethinking the relationships among the content, its teaching and the subsequent learning (Mortimer and Scott, 2003; Ogborn et al, 1996; Kress et al, 2001). Giving to the lecturers an opportunity to be the subjects of their own change and to question their own practice, contrasting it with theoretical elements and reflecting about it, can bring these lecturers to build alternative didactics to respond to new focuses. Also, we perceive the teaching-learning process from the semiotic point of view, because of the scientific concepts cannot be limited to a single language or an only one form of representation. The languages of science involve verbal language, scientific symbolic language, as well as other, as the languages of visual representation, the languages of mathematics, and the languages of experimental operations. All these semiotics resources are rhetorically orchestrated in science classes. The role of the lecturer in this process is very important.

Argumentacion Theory

To build our analytical framework, we base mainly on the argumentation theory of Perelman & Olbrecht-Tyteca (1958/2000) and Perelman (1982). It aims at studying the discursive techniques that allows increasing the adhesion of the audience's minds to the theses that are presented for their acceptance. This theory combines a rhetorical approach with an argumentative one, and which has proved to be a good framework to support the analysis. This theory introduces fundamental elements as: a) premises, formed of the agreements accepted by the audience, which will be the departure point of argumentation, b) theses (concepts, scientific points of view), c) *adaptation of audience (the students)*, in terms of rhetoric the lecturer explanation has to convince students of their theses and this is accomplished first by *preparing the audience* for the discourse, it considers that a discourse is effective when it is focusing on the audience knowledge, to which it directs the persuasion techniques, and considers necessary to find the most appropriate ways to create participation of the audience in the discourse, d) discourse presentation form, it is referred to prosody, verb forms, rhetorical devices and strategies used to achieve *communion* with the audience, e) *the presence*, which is necessary to give to the premises in order to increase its rhetorical value or convincing.

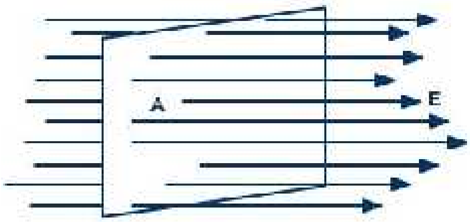
The Presence and Multimodality

The presence is an essential element in the argumentation, based on the selection of concepts and how to present them in order to persuade and convince the student. Before to go to classroom, the teacher have to select, organize and classify content, and to select, consciously or not, a variety of rhetorical means to present the concepts to their students (the audience). Making this selection with a view to persuading the particular audience particular, the lecturers are using the presence from a methodological point of view. Other derivation of the presence notion defined by Perelman is the *presence of second order* introduced by Gross &, Dearin (2003). It refers to accumulative effect of simple presence of elements that produces a greater effect or synergy. We give presence in the explanation when it cause an effect on the student: drawing their attention to the class, reminding the name, equation or mathematical variable, drawing a system, recreating a moving picture, setting in their mind, among others. This type of presence is related with the building of meanings and the multimodality in the classroom. In their research Kress, Jewitt, Ogborn and Tsatsarelis (2001) show us rhetorical functions of objects that mediate the action in the classroom, to give "presence" (make that it becomes more "real) at the conceptual entity, from which students can see new features and qualities that are useful in their conceptual building. Among several presence' resources they are a) showing the imaginary, where an identity is present to the student through the action with the body which acts as a rhetoric sign, and b) the demonstration using physical objects.

In the experimental sciences context, a research line has been undertaken in the University of Barcelona (Fagúndez, 2006; Castells et al, 2007, Konstantinidou et al., 2010). Their results constitute the main antecedents for our investigation. With the obtained results (Rangel & Castells, 2005, 2010) is created a new small research that tries to study the lecturer's action in the classroom from the multimodal perspective when lecturer is scientific meanings building.

Electromagnetism topic: the Electric Flux

In most college physics textbooks (Fishbane, 1993; Sears, 2005; Serway, 2005), we found the use of an initial system to conceptualize the electric flux, consisting of a rectangular surface which is crossed by uniform electric field lines. Electric flux through an elementary area is defined as the scalar product between area vector and electric field (*figure 1*). The meaning of concept electric flux is constructed using both the notion of electric field and electric field lines and a new concept which is defined to treat area of a surface as a vector, where the vector length represents the magnitude of the area and its direction is outward drawn normal to the surface.



$$\phi_E = \iint \vec{E} \cdot d\vec{A}$$

Figure 1. *System used to explain Electric Flux*

3. RATIONALE

The relevance of this study is its contribution in the lecturer training, like a piece of a whole. We consider that the lecturers training has to be done taking into account the knowledge accumulated by lecturers in the self educational context and which is demonstrated with their actuation in the classroom. Our global objective is to improve the physics lecturer action in classroom, by means of starting from awareness about the construction and creation of the explanation in the classroom like scenario and the relationship with their students trying to reach to the development of the scientific knowledge and abilities necessary for an engineer in the students. A way is to characterize the physic teaching in the engineering classroom context trough the analysis of the lecturers' explanation.

4. METHODS

The research is qualitative, based on case studies; it is an analytic and descriptive study, aiming to capture processes and their development. The experience is carried out in Venezuela, in the School of Engineering at the Universidad de Carabobo, resting on the discourse of three Physics lecturers' (Laura, Montse and Pere) teaching the electric flux topic in electromagnetism unit. Data was gathered through direct, non participative, observation, supported by the video recording of classes and researcher's field notes. The information was divided in segments according to the topics, and separated in episodes of one minute each one, called: [D01], [D02],.., [D019]. The final data are presented seeking to be useful for understanding of any science teacher. Through of a transcription process, the table that includes the lecturer speech, drawings on the slate, lecturer movements, and photography shots is built. *Data analysis:* The analysis will be done from the multimodal perspective and specially taking into account the presence in second order in the multimodal action of lecturer. For this study we sought issues such as:

Secuence: a) order: How the lecturer combined the premises, and thesis that she/he goes building?, b) time: How the temporal space is used?, c) the Rhythm: Can we identify lecturer explanations with global functions? Are this ways presents in the three lecturers?

*Multimodal action in the building meaning: a) r*esources used: physical objects, mimic, draws; b) the function of resource: To develope scientific contents or specific abilities.

<u>*Pere's explanation analysis:*</u>
Pere, a young lecturer with Physics degree, he has classes early in the morning. The class has started one and quart hour ago, and there is a lot of noise, because PERE has asked to make four-person teams to deliver some books evaluated exercises. "*Pere: OK, now we let's talk about something else"*. The students' noises continue. He erases slate and then writes [a]Gauss law - Electric flux" - and he goes behind the desk waiting in silence for three minutes. Therefore a little more quiet students Pere began his explanation emphasizing: "*FLUX, is a..."*. He introduces the flux concept [D01], represents the system on the slate [D02], and then continues ([D03] to [D08]) his explanation on the slate describing, comparing and differentiating the system's variables such as surface, area vector, field and field line.

<u>*Montse's explanation analysis:*</u>
Montse, an experienced lecturer with Physics degree, ends her classes just for lunch. The class has started two hours ago, and when Montse says she has a new topic, are heard students saying: "*Nooo!"* She looks a bit tired, and everyone in the classroom needs a break. She will. She gives them encouragement, and introduces the concept with a question, "*what it means for you the word flux*?" [D01]. In D02 to D04 Montse recreates the image of a river and each one of them on holiday in the river banks, "the sound of river "rrrrrrrr",... emphasizing with her body and swinging the arms simulates waves "these are the *waves river"* "*..But the river always gives a sense of calm, of peace* !.." (Emphasized the peace word opening her arms and mouth) *"It is very* nice!" (Pause). The students begin to laugh, relax with the representation of the holidays and the lecturer's humor sense. She combines every day speech with a little black humor without losing sight of the topic, *"How do you measure if a river is more abundant than another?"* In D05, D07, she continues the representation by measuring, this time with two identical "imaginary rings", she dipping one in the Orinoco River and another in the Amazon River. In D08, D09, after she gets students the variable time, she introduces the electrical flux concept, and then she starts electric flux definition. She justifies why the time is not necessary since it is the electrostatic field measure. In D12, D15, Montse describes the system drawn on the board [D10]. She reinforces this explanation with representaton of surface using a folio. She draws on this, littles rectangules representing small areas through which it passes <u>only one</u> electric field line (she emphasizes with her finger). She represents the system on the slate, and then continues her explanation using the folio on slate to describe, compare and differentiates area vector, electric field and electric field line (she emphasizes pointing her hands).

<u>*Laura's explanation analysis:*</u>
Laura, electrical engineer, is one of the oldest Physics Lecturers of engineering Faculty. She has her class in the afternoon. She introduces the electric flux presenting premises unknown for students in [D01]: "*Let us see now the Gauss law and this is the first of Maxwell's equations. Okay? (...) but first let's talk about a quantity which is closely related to the electric field and in particular, to the number of field lines passing through any surface ..."*
In D02 Laura introduces the electric flux: "T*his physical magnitude that is proportional to the number of lines arriving, departing, or coming to the surface, is precisely known electric flux."* She writes on Slate emphasizing the bamed variable and its nomenclature before to draw the system. In D03 she connected electrical flux with magnetic flux which is a new

concept to be studied, she continues drawing the system while she describes it. From D04 to D06, Laura makes a detailed description of area vector, and of its components using the slate to write what she says. She uses a marker to represent the area vector on slate, and she draws a coordinate axis. She leaves the slate and placed in front students asking them: "H*ow is the angle between the vector and the electric field area?.*. It is the same f*or each point on the plane surface."* In D07 to D12, Laura makes a system recreation formed with many elements. She takes a folder as "a surface" and she draws on air a uniform electric field. She uses the walls of sides and her arms to set in the student, the image of the electric field lines crossing classroom. From there, she continues ask them and verify their responses. She writes on the folder a "X" to indicate external face, and uses her arms and finger to represent the area vector and the electric field. She emphasizes with both her body and voices everything she is saying. In D12 to D16 Laura turns to slate and draws explaining this. Again her actuation on the slate is detailed; she draws other positions of same system. She uses the folder to help the students' understanding of drawn it, then she analysises the behavior of electric flux according to variables system such as surface, area vector, field and field line.

5. RESULTS.

This work studied the explanations of three physics lecturer on a same topic using the same system, the findings about the meaning building process are:

The secuence in the Electric Flux explanation and the Rhythm. We identified five phases in the explanation construction as: a) the topic's introduction b) the flux definition, c) the system presentation on slate, formed by the named initial variables and drawing the system on slate, writing mathematical expression, d) spatial representation, using 3D image recreation or making mental images in three dimensions, about the flux concept, e) development of behavior of electric flux supported by mathematical concepts. The figure 2 shows the sequence of the explanation identifying in each phase the multimodal resources, and the most outstanding actions of the lecturer. This secuence shows that although they met the goals of curriculum, each lecturer characterizes a differernt teaching style in which the lecturer organizes, select content, the time spent and resources in each phase, and its combination. We called this the Rhythm of class. These lecturers, each in his/her style use a) the same time to the concept's introduction and to the initial system description, b) the same time to mathematical development, and two of them spent the same time to the recreation of mental images in three dimensions, except Pere, who seems no need spatial representation, may be because of the support of the quality and detail of his drawings.

Multimodal resources used and the Presence. The physics teaching process includes an effort in the multimodal action in the classroom, to create physical systems from imaginary achieving in a high level presence. In this way, many multimodal resources are interacting between them and the students becomes immersed into them being integrated in this imaginary system. The dynamic combination of multimodal resources in the action of lecturers enforces the *presence* of electric flux to students, facilitating the meanings construction. Although, each lecturer had different ways to create the explanation about the same topic even using the same system, we noted an effort along of their explanations for keeping the student attention they were use of their voices, gazes, the inclination of their body, involving the students in the explanation that then will be considered as a whole. The representation modes used were: a) spatial representation, through recreation in scene, b) the use of the body and arms to give presence to the directionality of the electric field and surface vector, c) the spatial representation, using physiycal objects and imaginary objects, d) the representation on the slate, with colorful drawings, using objects physical too.

Figure 2. Multimodal resources used and explanations' secuence of three physics lecturers.

Preparing audience (the students). The lecturers know their students, its values and hierarchies; this knowledge helps them in the selection of argumentative tools to use, especially the starting points of explanation, to achieve the attention to their verbal explanations. We observed situations in which the students (noisy, tired) were not prepared to pay attention, however the lecturer used resources (sense humor, black mood, onomatopeya, silences, voices) for to reach the engagement necessary with the students and give start the reflexive process of the explanation. The lecturer's discourse is not only built through the transposition of the scientific knowledge to the specific educational context, but of verifying if the audience "receives" the ideas of his/her discourse. Is this continuous search for the agreement (communion with the audience), and the confirmation of the student's attention, what guides the professor's discourse, through feedback by the visual contact, or with the use of repetition and rhetorical question.

***Function of multimodal action in electric flux explanation*.** There were different representation modes of premises and varied functions were identified, some are: a) building the area vector definition, and to reinforce the electrical field line concept, b) differentiating the area vector with the electric field at different points, c) relating the electric flux equation with an adequate surface to solve the integral, d) differencing electric flux cases with different configurations of electric field. We highlighted a common feature in the Lecturers' explanations, the reinforcement of spatial representation and use of many multimodal resources at time.

6. CONCLUSIONS AND IMPLICATIONS

The physic teaching process include an effort in the multimodal action in the classroom, for create physic systems from imaginary, achieving a high level *presence*. In this way, many multimodal resources are interacting between them and the students are immersed into them forming part of the imaginary system. Discourse analysis, allows us to know of lecturer's

Rhythm uses for build meanings and to keep the adhesion of students. This dynamic of teaching gives strength to the *communion* to facilitate the learning. A contribution of this research is the knowledge acquired by the researches through of analysis' process about the teaching process, contrasting it with the own one. The lecturer makes use of all available resources in the classroom to help students to create three-dimensional images of systems that do not exist physically and that it will contribute to the engineer special vision, where the different forms of representation are more important than words. The results of the investigation open us new ways for lecturers' training in order to improve the physics lecturer's praxis, relative to their communicative capabilities for to build a discourse that could be effective for a specific audience.

THE ROLE OF GRAMMAR IN SHORT VERBALIZATIONS WHILE AUTONOMOUS SCIENCE LEARNING

Antonio E. Rueda Muñoz[1] *and Manuela Welzel-Breuer*[1]
[1]University of Education Heidelberg, Germany

Abstract: In contrast to actual research on semantic interpretation or discourse analysis of students' verbalizations in science learning, this contribution is focused on a grammatical perspective. The present paper represents a small part of a broader exploration of motivation and learning of Colombian students working with a German computer-based learning environment. Investigated students (secondary school) worked autonomously during approximately one hour with one unit of the learning environment. 18 students have been video-taped (6 dyads and 2 triads). Their verbalizations were very short and abrupt, for which reason a new linguistic approach has been applied. The aim of this paper is mainly to evidence the method used. Transcripts of verbalized contents of the unit have been coded using a theory-based category system. For the development of the category system, some patterns of the Systemic Functional Grammar (Halliday 2004) have been adapted. Therein grammatical structures of single clauses imply the representation of eventuality (processes by verbal groups, participants by nominal groups and references by circumstantial phrases). Moreover, conceptual networks are given by the cohesion of complex clauses (by means of conjunctions). The reliability of the category system showed on average moderate values. Results evidence the use of single unspecific nouns, material verbs and lacks of cohesion within single clauses and among sentences. This analysis represents a first approach to the diagnosis of conceptual development in its first states, namely the construction of eventuality while abruptly speaking.

Keywords: Autonomous learning, Systemic-Functional-Grammar, Verbalizations

INTRODUCTION

The explorative analysis of the use of a German computer-based learning environment in Colombia has been conducted. The learning environment was adopted within Colombian science classes (8^{th} and 9^{th} grade, 10-11 years old students) in four different schools. The investigation was divided in three parts: (1) external conditions of the schools, (2) motivation of students in terms of self-determination while working with the computer-based units and (3) learning processes. In this contribution, only selected results related to (3) learning processes and the corresponding empirical category-based analysis of video-taped sessions will be presented.

Video-taped students' groups should work approximately one hour on the contents, using digital and real material concerning one unit of the learning environment about the "red eyes'-phenomenon" (on photos made with flash in dark surroundings). The learning aim was to combine light properties with those of the human eye. Students had to deal with nine exercises within the unit.

Students talked abruptly about the themes of the recorded unit. Most of them didn't express themselves using completed utterances. The following examples of the verbalizations concerning the reasons for the "red eyes'-phenomenon" (1^{st} exercise of the unit) present difficulties for a content analysis (vs. hermeneutical analysis)[1]:

- 1^{st} Example: "I think… I don't know… because the flash is more… is more oriented to the eyes, therefore… what do you think?"

[1] Examples in Spanisch. *1^{st} Example*: "Yo creo… no sé… porque el flash es más... está más orientado a los ojos... por eso... ¿Usted qué piensa?". *2^{nd} Example*: "La luz rebota". *3^{rd} Example*: "Luz".

- 2nd Example: “The light is rebounded”.

- 3rd Example: “Light”.

Students expressed themselves autonomously. They talked some minutes about the task and then wrote their conclusions into a predetermined field for answers of each exercise. They were not asked to think aloud. They should explain their findings to their teachers, but in most of the cases they did not do it. Subsequently, some difficulties emerged for the data analyses and corresponding empirical approaches for a scientific investigation of such verbalizations couldn’t be carried out: (1) Most of the utterances were not *argumentations* (e. g. Kelly et al. 1998; Toulmin 2003; Jiménez-Aleixandre & Erduran 2008; von Aufschnaiter et al. 2008), but verbalizations of perceptions or incomplete statements. (2) In some of the cases the concepts expressed were difficult to interpret (e.g., 3rd example), so that *conceptual change* cannot be determined (e. g. Vosniadou 2007; Treagust & Duit 2008; Tiberghien et al. 2009). Moreover students did not show a need of conceptual acquirement.(3) They had not the quality of *metaphors* (e.g. Tobin & Tippins 1996; Thomas & McRobbie 1999; Geelan et al. 2006; Tobin 2006). Most of expressions are just uncompleted ideas. (4) A scientific process meaning a systematic process of *problem solving* couldn’t be directly observed (e.g., Bransford & Stein 1997; Lederman 2007). (5) The verbal *interactions* among students (von Aufschnaiter 1999; Kelly 2007) were frequently incomplete. A discourse couldn’t be detected in most of the cases. (6) Most of *learning processes* appeared as declarative (mental) vs. motor (actions) (Welzel & Roth 1998; von Aufschnaiter & von Aufschnaiter 2003). Some of these declarative processes couldn’t be interpreted in terms of complexity (as shown).

Because of these caveats, it has been decided to investigate linguistics within the verbalizations in a first step of the study. The role of language in science education has already been established (e.g. Carlsen 2007) especially based on Vygotskij’s theoretical appreciations (Vygotskij 1978). But most of empirical approaches are concentrated on interactional, semantic and conceptual meaning of verbalizations. In contrast, the present study of basic grammar properties of verbalizations contributes to the representation of things and events observed or thoughts. This issue has not yet been considered in science educational studies.

The investigation of grammatical content of verbalizations would concern the study of “static” states, that is, “learning states”. The development of those learning states should yield learning processes. This step of linguistic grammatical analysis of learning states is exclusively going to be presented in this contribution. Other steps of the investigation (contextual interactions and interpretation of semantic meanings) have been analyzed, but are going to be presented in future publications. For the present analysis the Systemic Functional Grammar has been used (Halliday 2004).

RATIONALE

Halliday and Matthiessen are the most important exponents of the development of a complex taxonomical architecture of language named Systemic Functional Grammar, SFG (e.g. Halliday 2004; Matthiessen et al. 2009). Herein the functionality of grammar (how language is used) and its growth over generations shaping the communication system are the fundamental properties. In the SFG, the representation of experience through language has been defined and categorized with reference to the grammatical functions of the constituents of verbalizations. In this contribution merely few aspects of the SFG have been accounted for the empirical analysis of learning states. The most important issue is how simple clauses (i. e. the students’ verbalizations) can be categorized for a quantitative content analysis.

Halliday and Matthiessen have defined five dimensions of language in terms of functions of phonemes, morphemes and clauses (which are “structure, system, stratification, instantiation and metafunction”) (Halliday 2004, p. 24). In the present contribution the stratum of “lexicogrammar” (“meaning transformed into wording”) (ibid.) represents the key for quantitative analysis. Furthermore the present approach is concentrated on the “ideational” metafunction (language as “construction of human experience”) (Halliday 2004, p. 29).

In the framework of the SFG, a simple clause with the quality of representation (of human experience) can be defragmented in processes (verbal groups), participants (nominal groups) and circumstances (adverbial and prepositional groups). The following paragraphs shortly explain the categories of processes, participants and circumstances used and adapted for the grammatical study.

- There are six types of representational *processes* ("material, existential, relational, verbal, mental and behavioural") (Halliday 2004, p. 172, ff.). Only material, existential and relational processes have been selected for the present analysis (processes of happening, creating, changing, doing, acting, existing, attributing or identifying). Verbal, mental and behavioural processes (meaning, thinking, feeling, seeing, and being conscious) reinforce in some extent the opinion or intention of the verbalization but don't account for additional information concerning the experiential content of the verbalization.
- *Nominal groups* have been categorized within representational clauses in the SFG as "deictic" (determination of a thing or event), "ordering" (potentiality of the elements of the group) and "qualifier" (additional information about the thing or event) (Halliday 2004, p. 312, ff.).
- Enhancing *circumstantial groups* (groups that answer the questions what?, where?, how?, why? or under what conditions?) are classified into "extent and location" (construction of the process in time and space), "manner" (how the process is actualized), "cause" (why the process is actualized), and "contingency" (conditions for the actualization) (Halliday 2004, p. 259, ff.).

Complex clauses are linked by "logogenesis" ("creation of meaning in the course of the unfolding of text") (Halliday 2004, p. 530, ff.). Logogenesis actually occurs in all strata (not only in the lexicogrammar) and all metafunctions (not only the ideational). In the case of complex sentences in which the subordinate clauses enhance the meaning of the main clause, the *conjunctions* give information about the relation of a clause to the previous one (Halliday 2004, p. 540, ff.). The system of conjunctions is similar to the enhancing circumstantial group seen before (spatio-temporal, matter, manner, causal-conditional).

Verbal groups as processes, nominal groups as participants, circumstantial groups as attendants and conjunctions as logogenetic nexuses for complex construction of meaning are the basic components of clauses which grammatically represent the expressed actuality. These components have been quantitative analyzed in the empirical study.

RESEARCH DESIGN AND METHOD

An explorative investigation has been accomplished. The German computer-based learning environment was implemented in four schools in Colombia. Eight classes took part in the investigation (one 8^{th}, five 9^{th} and two 10^{th} grade classes). 18 students (4 girls', 1 boys' and 1 mixed dyads; 1 boys', 1 girls' triad) have been videotaped while interacting with one unit of the learning environment during approximately one hour (total recorded time: 8h19min14sec). The unit concerns the "red-eyes'-phenomenon" and the parts and functions of the human eye. It contains nine exercises: (1) Previous knowledge; (2) Internet inquiry; (3) Use of a model of the eye; (4) Parts of the eye; (5) Test about the parts of the eye; (6) Similarities to animals' eyes; (7) Functions of the parts; (8) Test about the functions of the eye; (9) Reflexion about the red-eyes' phenomenon.

Deductive content analysis has been conducted (Mayring 1983, 1987). The recorded verbalizations of students related to the content of the learning environment have been transcribed for their analysis (time of analyzed verbalizations: 40min23sec). The analysis of the Spanish transcripts has been done by one researcher. The grammatical categories introduced in the rationale have been slightly adapted to the situation for quantitative analysis (Table 1). The following category system has been used:

Table 1: Categories and Subcategories adopted for the analysis of single and complex clauses adapted from SFG.

Single clause			Complex clause
Verbal (Process)	*Nominal (Participants)*	*Circumstances (Adverbial, prep. Phrase)*	*Conjunction's type*
1. Existential	1. Determination	1. Localizing	1. Reference (spatial-local)
2. Material	2. Property	2. Manner	2. Contingency
3. Relational	3. Quality	3. Contingency and cause	3. Manner
			4. Causality

The components that appear in each verbalization (verbs, nouns, adverbial or prepositional phrases and conjunctions in complex clauses) have been recognized using a category-based analysis. Total amount of categorized components have been calculated as a function of exercises and of groups. In order to represent a manageable overview of the results, the total amount of categorized components has been multiplied by the corresponding time-rates: (Total recorded time) / (Time of corresponding verbalization).

Before the last analysis was implemented, a reliability test of the category system has been carried out. For it, it was necessary to use German verbalizations (so that they could be coded by German researchers). Therefore, previous recordings of German students' groups working with the learning environment have been used. Transcripts of verbalizations of six students (2 girls' and 1 boys' dyads) have been analyzed by four researchers. The total transcribed time was 10min42sec. Fleiss' intercorrelation coefficients, significances and effect sizes have been calculated for each subcategory. In summary, it can be concluded that agreement by coding (Fleiss' kappa over 0.5) presented a high level by some frequent subcategories: Material (within Verbal), Determination (within Nominal), Contingency and cause (within Circumstances) and Contingency (Conjunctions' type). These subcategories showed high statistical significances ($p < 0.001$) and effect sizes (over 0.4). Other subcategories were coded less frequently and got moderate values for Fleiss' kappa and effect sizes. Only one subcategory (Quality within Nominal) showed no significant values. After coding, troubles of researches by coding have been discussed. As conclusion of this reliability test, the definitions of some subcategories have been more concretized.

After this process a final reliability test has been conducted. Herein N=55 verbalizations of the Colombian sample have been coded by two Spanish speaking researchers. Cohen's κ show high significant results for all four main categories (Verbal: .692**, Nominal: .726**, Circumstances: .576**, Conjunctions' type: .451**; (**) denotes high significance). Despite the good agreement of the test, it has to be reported a very high coincidence (more frequently than random) of intercoding. Assumedly the sample used for this test of intercoder-reliability contained several patterns, which could be easily recognized by both researchers. Further research is therefore needed in order to validate this first test. Moreover, the future samples analyzed with the present method should include more manifold verbalizations, e. g. by means of Think Aloud protocols (Ericsson & Simon 1987).

RESULTS

The following diagram (Fig. 1) shows the results of coded verbalizations multiplied by time-ratio over the categories and subcategories of the system used. The bars represent the nine different exercises of the unit. The purpose of the diagram is to show a comparison of the rationalized codes in dependence of the subcategories for each exercise.

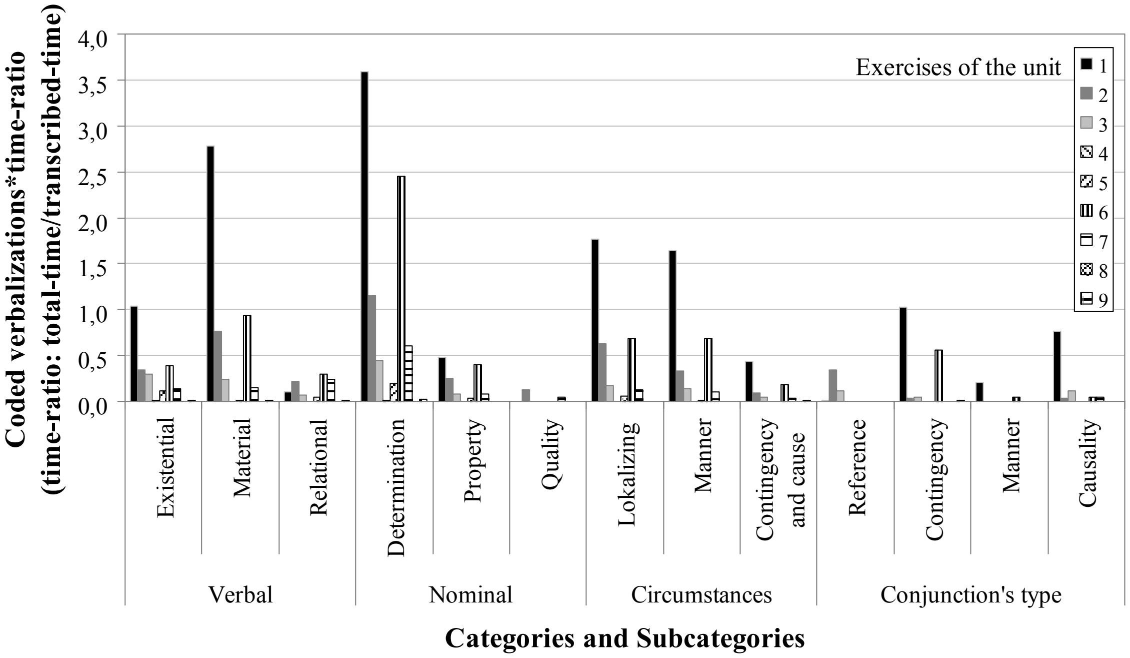

Fig. 1: Time-normalized coded verbalizations over the presented categories and subcategories. All results are presented in terms of the exercises (legend).

The diagram shows that material verbal groups (e.g. verbs expressing, what occurs) and determinative nominal groups (e.g., single nouns) achieved the highest levels. Moreover students verbalized more often during exercises concerning prior assumptions (1st, about red-eyes'-phenomenon and 6th, about animals' eyes). Within the category "Circumstances" localizing and manner adverbs (e.g. describing where and how something occurs) more frequently used. It also has to be highlighted that complex clauses within the category Conjunction's type have been detected in less verbalizations. When students constructed complex clauses they used contingency (e.g., "if… then") or causality (e.g., "because…"). They almost didn't speak by means of references (e.g., "where…", "when…") or analogies (e.g., "as…").

CONCLUSIONS AND IMPLICATIONS

A lack for analyzing short verbalizations of students in science education research has been stressed in the present paper. A grammatical approach for this task has been illustrated. The Systemic Functional Grammar (HALLIDAY 2004) has been used for the development of a category system for quantitative analysis of short verbalizations. Therein the lexicogrammatical content of words expressed (verbal and nominal groups, circumstances' phrases and conjunctions linking complex clauses) could be examined. This new method showed an overall moderate reliability.

It can be interpreted from the results that students mostly spoke asserting common nouns and describing happenings by means of verbs. The expression of coherence between simple events (subcategory Relational in Verbal groups) was rarely coded. Complex cohesion of events using conjunctions was insufficient, too. Analogies (Manner in Conjunction's type) were used very seldom. These lacks of coherence and cohesion in the verbalizations can be taken as deficit of mental networking. Instead of that, most of verbalizations consist of expressions of perception and static states in the actuality (by means of material verbs and determinative nominal groups).

This analysis has shown how basic grammatical issues can be used for the identification of initial states of thinking based on the linguistic study of verbalizations. In fact, syntactic and lexicogrammatic processes are firstly recognized by the brain (FRIEDERICI & ALTER 2004; BARSALOU et al. 2008; BORNKESSEL-SCHLESEWSKY et al. in press). Therefore basic grammatical (syntactic) patterns could also be considered previous to conceptual study for educational purposes.

TEACHERS' CHANGE OF CONCEPTIONS ON ARGUMENTATION AND ITS TEACHING

Francisco Javier Ruiz O[1], *Conxita Márquez* [2]*and Oscar Eugenio Tamayo A*[3]
[1,3] Department of Educative Studies, University of Caldas, Manizales, Colombia
[2] Department of Science and Mathematics Education, University Autonoma of Barcelona, Bellaterra, Barcelona, Spain

Abstract: this study shows the changes in the conceptions of the epistemological, conceptual, educational and structural aspects of five primary teachers. Those said changes occurred before and after those teachers took part of a process of critical discussion of their teaching practices on argumentation in Science class. In order to identify the changes in the four aspects, a content analysis to a questionnaire applied at the beginning and at the end of the process was done. The results showed a significant change in the components: epistemological, conceptual and educational, and not that much in the structural one. Apart from that they ratified the importance of offering spaces of participation for the teachers to discuss, evaluate and propose mechanisms to improve their practices in the classroom.

Keywords: Argumentation, teachers' conceptions, dialogic education, argumentative structure.

INTRODUCTION

Background and rationale

Many linguists and epistemologists have recognized the central role of argumentation not only in the construction of science, -since it allows substantive relations between models and evidences-, but also in the educative field because the argument is a form of discourse that needs to be appropriate for children and explicitly taught through proper instruction, structured tasks, modeling (Von Aufschnaiter, Erduran, Osborne & Simon, 2008; Erduran, Simon & Osborne, 2006), and argumentative experiences (Aleixandre & Díaz, 2003). Additionally, researches done in the field of the teaching of argumentation in Science Class, show the need, not only to teach how to do it, but also to involve teachers so that they can be conscious of their conceptions about argumentation (Driver, Newton & Osborne, 1998; Simon, Erduran & Osborne, 2006; García-Mila & Andersen, 2008).

Two more reasons that support the development of this study are: First, that with this research, although we will focus only on argumentation in Science class, we want to contribute to the development of scientific thinking in children which is one of the principal goals in the Colombian Educative Policy. Second, we believe that with this work, we can give extra opportunities to improve teacher practices, because elementary school teachers do not have any training in argumentative processes. That is why, teachers do not emphasize on the importance of dialogical processes in their classroom.

From this perspective, this research has as general objective, to identify changes in the epistemological, conceptual, educational and structural aspects of the arguments elaborated by the teachers who take part in a process of critical reflection, on the teaching of argumentation in Science class.

Research context

This investigation was developed in a state institution called Fe y Alegría in Manizales, Colombia. This institution has approximately 2250 students and it is located in a marginal zone of the city. There, we worked with five primary teachers, in 4th and 5th grades. Four teachers are graduated from a special high school where their principal emphasis is Pedagogy; one of them is graduated of Academic High School.

METHODOLOGY

To achieve the specific goal that was presented before, the following activities were implemented:

- Initial and final questionnaire. We applied the same questionnaire at the beginning and at the end of the process (seven months after starting the critical process). The questionnaire had seven opened questions,
- Classes' recordings. We recorded the first class before starting the critical discussion process, because it was important to know how to start with the teachers in this process.
- Meetings. There were some critical discussions about the role of argumentation as a tool to teach in class of Science. Besides, the discussions were also related to the structure and function of the argumentative components. In order to do it, teachers had three meetings. Each one lasted five hours.
- Design and application of activities. Each teacher designed and applied the first activity for the teaching of argumentation in her/his own class (the activities were video-recorded).
- Observation and analysis of the recorded classes. The participants observed the videos and then, discussed their viewpoints in groups. They also gave some proposals to change or overcome their weaknesses.
- Design and application of activities. Again, each teacher designed and applied the second activity for the teaching of argumentation in class of science (activities were video-recorded).
- Analysis of the video recordings and application of the final questionnaire seven months after the process have started.
- Interview. After each class we conducted an interview with teachers for them to reflect on their performance.

Data analysis

To characterize and identify the changes in the conceptions of teachers, a content analysis to the questionnaire applied at the beginning and at the end of the process was done. The transcription and codification of the information was done with the help of the Atlas-ti software. To do the content analysis and subsequent quantification of the codes constructed, we applied the formula: % Code = code number of citations X 100 / total citations, which allowed the construction of some frequency tables.

RESULTS AND DISCUSSION

The table shown below shows the results of the four components discussed in the initial and final questionnaire:

Component	Category	Subcategory	Results questionnaires	
			Initial (100%)	Final (100%)
Epistemological	Relationship argumentation – science	Yes	69,23	92,31
		No	30,77	7,69
Conceptual	Recognition of argumentation as/a	Informative Process	80	0
		Dialogic Process	20	42,9
		Learning tool	0	57,1
Educational	Relationship teaching-argumentation	Yes	100	100
	Criteria taken into account in their teaching: Student (S), Teacher (T), Knowledge (K), Context (C)	S	22,22	0
		S-T	44,44	27,27
		T-K	33,33	O
		S-T-K	0	45,45
		S-T-K-C	0	27,27
	Classroom management - Type of activities	Individuals	50	10
		Groupal	50	90
Structural	Level of arguments	1	33,11	9,37
		2	41,67	53,13
		3	13,9	31,25
		4	8,33	6,25
		5	0	0

“Table 1. Results obtained with the initial and final questionnaire”

Next, a short discussion of the findings obtained in the first three aspects: Epistemological, Conceptual and Educational, is going to be introduced. Some examples of the teachers' answers will be included to support our discourse.

1. **Epistemological aspect:** The situation to investigate this aspect was:

   There are two general concepts of science:

   - Science is a cumulus of absolute and objective knowledge which is the result of a linear process that comes from the observation and experimentation about the real world to scientific theories.
   - Science is the result of a negotiation process among the members of scientific communities where models and theories constructed as a representation of the world are presented, discussed and validated.

> Which one of the two previous concepts, do you think is the most suitable for the teaching and learning processes in the science classroom?. Support your answer.

One of the answers given by one of the teachers in the first application of the questionnaire was:

> Teacher: The two processes are important for the construction of science, given the fact that in the science teaching process there should be experimentation, observation, comparison, analysis, comprehension and dialogue with other people who are performing the same experiment and investigation in order to arrive to some conclusions.

As observed in the teacher's answer, for her, both processes are important in the construction of scientific knowledge. She justified her answer by affirming that, to arrive to a conclusion, you need some spaces to experiment, observe, understand, and interact with the scientific community. She added that the community –or "people" in her own words- have to be involved in the experiment or research experience. However, this is not always true in the process of construction of science.

In the second application, one of the answers was:

> Teacher: Yes, they are. (This teacher here referred to the two processes introduced in the question. She said both of them are important). They are important because the person who belongs to the scientific community, needs to observe and experience first and then, by doing so, that person would be able to introduce, discuss and validate his/her ideas in a group.

In the answer of that teacher, she stated not only the importance of both processes, but she also recognized the importance of debate and group work to knowledge validation. That relationship she mentioned is in agreement with some authors' ideas (Von Aufschnaiter, Erduran, Osborne & Simon, 2008). They claim that arguments that have been previously discussed, contrasted and validated in the scientific community are useful tools to the promotion and development of knowledge. Thus, the answer of that teacher shares the current theories on argumentation nowadays. According to those tendencies, argumentation is seen as a supporting mechanism to keep a qualified scientific knowledge and also as a scenario that promotes mobility from an interpsychological to an intrapsychological perspective. From that point of view then, argumentation is taken as a dialogic activity (Erduran, Simon & Osborne, 2004).

2. **Conceptual aspect.** The question exposed was:

If you were invited as a lecturer to an event on argumentation in the science classroom, what kind of explanation would you give of what it is supposed to be argumentation in the science classroom?

In the initial questionnaire, 80% of the texts produced by the teachers conceived argumentation as a process whose attempt is informative (perspective that tends to a structuralistic view of argumentation):

> Teacher: Argumentation is to provide a set of reasons or evidence to support a conclusion or some assumptions. By means of them, people try to decide what opinions are better than the others.

Only one of the answers (20%) assumed a concept of argumentation as a dialogic process, approaching to a functional perspective of argumentation, for example:

> Teacher: Argumentation is a clear and accurate concept of the issue which will deal, argumentation is to convince others to reach a conclusion.

In the final questionnaire, we found texts that demonstrated a dialogic perspective of argumentation, that is to say, they conceived argumentation as a social activity that requires the generation of a suitable atmosphere for its development. An example of this approach is found in the following extract:

> Teacher: Argumentation in science classes is to express what each one understands from his own daily life, refuting concepts if needed. It also means to be able to explain why things happen, and by doing so, to create socialization settings to generate an appropriate atmosphere where everybody can discuss.

Similarly, identified in the final questionnaire, the emergence of a new conception of argumentation as a learning tool (57.1% of the answers show this trend), that evaluates knowledge, for example:

> Teacher: Argumentation in science is a tool for evaluating knowledge. It is also a social process that is affected by ideas, prejudices and instances; it potentiates changes in the conceptions of individuals, leading them to rethink their knowledge about their surroundings.

3. **Educational Aspect.** Two question were presented to teachers:

- State two things science teacher should take into account in order to teach argumentation to his pupils?
- If one of your main objectives in your classes is to foster the argumentation process in your students, write two activities which might help. Support your choice for each of the activities.

After the first application of the questionnaire, teachers centered their criteria towards Students (22, 22%), the relation between S-T (44, 44%) and T-K (33,33%). An illustration of the first aspect is presented below:

> Teacher: The children's intellectual development and the development of their comprehension and analytic skills.

This answer shows the teacher's tendency towards students. This sentence implies that according to that teacher, learning depends on the development of the individual. This way of thinking contradicts the Vigotsky's sociocultural theory. According to Vigotsky, learning is a process and this process implies social interaction. Additionally, that interaction contributes to the person development. Therefore, learning is based on dialogic processes.

One of the things that emerged from the application of the questionnaire is the relationship student-teacher-knowledge and context:

> Teacher: We should create a class with appropriate conditions, with the teacher's help. We should help students to identify data and affirmations, doing group work using guided-questions; students should learn to listen, speak and justify their assumptions; They should be able to choose the best options.

An outstanding element in the previous answer has to do with the teacher's role. It is understood here as a support or help to the construction of a class. According to this view, power relations in spite of being part of the class, they would not be so notorious because one of the characteristics of interaction are the symmetric relations between student-teacher (systemic model, Contreras, 1990, cited in Levin, Ramos & Adúriz-Bravo, 2008). Also, because in power relations, they (students and teachers) are co-participants in the creation of such interaction scenario (Wolfe & Alexander, 2008).

The second element of the answer refers to group work as a key element to develop argumentation in Science class (Osborne, Erduran & Simon, 204b). The third element refers to choose from different options. Regarding that, it is important to mention that one of the basic processes for the evolution of science is the choice of an appropriate model theory. This selection focuses on the model that better explains the phenomena (Giere, 1999). In sum, in the answer there was a concrete intentionality: "search for the best option". That intentionality is similar to the process followed in the construction of knowledge.

To refer to the activities, in the first application of the questionnaire, teachers talked about two kinds of activities: Individual (50%) and group activities (50%). Next, we are going to give an example of the first type of activities. With these activities we could observe learners as receptors of external stimuli and information. They do not have previous knowledge about the phenomena or theories introduced in class.

> Teacher: Do some experiments with plants or living organisms. It is good for children to observe what happen at the different stages in the process.

In the second application of questionnaire, we could see changes in the kind of activities. An example is provided below:

> Teacher: the most important is that the group can work with a coordinator or representative who collects concepts and writes them down. Participation and interaction are essential.

As noticed, according to that teacher, it is good to work in small groups, there, students could share their ideas and later, socialize them in class. This is interesting especially because it promotes the in pupils their abilities to synthesize, listen, value ideas and get into agreement.

CONCLUSIONS AND IMPLICATIONS

The results at the end of the process show significant changes in three components:

- **Epistemological**: in the final questionnaire the teachers recognized science is affected by communicative processes, teamwork and several debates with the scientific community, to validate results.
- **Conceptual**: the most significant change here was the emerging of a new conception, argumentation in class of science as tool of learning. This conception is related to the one exposed by some authors who see in argumentation a possibility to support intentions addressed to solving some problems of learning and understanding better these processes in the classroom. (Jiménez-Aleixandre & Erduran, 2008)
- **Didactic**: a significant finding in our research refers to the criteria for teaching argumentation. This criteria is strongly related to the elements student-teacher-knowledge and student-teacher-knowledge-context. Taking those elements into consideration mean a functional perspective of argumentation, where interaction is

important but not only the one between subjects, but also where it takes place (the context) and which is the knowledge involved in this communicative process.

- For the fourth component, **Structural**, although there is an increase of texts constructed by teachers, characterized by the presence of data, denial, and some justification (Level 3, Erduran, Simon & Osborne, 2004), but we don´t see important changes in the other levels, then we consider it is necessary to continue creating environments where teachers can, critically, propose mechanisms for the improvement and development of more complex argumentative texts.

From these findings we confirmed how important the teaching of argumentation in science class is. Involving teachers in processes of critical discussion, assessment and leading them to be aware of their own views, is the first step towards the improvement of their practices in science classroom.

RELATIONS BETWEEN THE ARGUMENTS SET OUT IN SCIENTIFIC PAPERS AND ARGUMENTS PRODUCED BY STUDENTS

Daniela Lopes Scarpa[1] *and Silvia Luzia Frateschi Trivelato*[2]
[1]UFABC/Brasil
[2]USP/Brasil

Abstract: The work presented here suggests that school culture regulates the way students access objects of scientific culture. As object of analysis, were taken two texts of scientists and ten texts produced by students on the same topic, the notion that the DNA molecule is the carrier of hereditary information. Toulmin's argument pattern (1958/2006) and the linguistic marks of Koch (2000) were used to identify elements of the arguments and their relations. The analysis of the texts showed that students make use of substantive arguments, while scientists construct their texts by means of analytical arguments. The use of different tenses of speech reveals the transformation of a functional biology into a historical narrative. The selection and use of lexical qualifiers made visible the shift from alethic to epistemic modalities, which presented different uses in scientific texts and in those constructed by students. It was possible to argue that the route taken by students to access scientific truths or to construct views of science involves different stages and processes of those covered by the scientists. If, on the one hand, it is not sufficient for the purpose of science education to provide the understanding of results and conclusions produced in the scientific sphere, on the other, not all the rules are accessible to students. Thus, science education must be seen as a process of constructing an idiosyncratic view of science that involves the understanding of its concepts and language, not by means of adopting this new culture, but to be able to interact with it.

Keywords: school culture, scientific culture, science education, biology education, argumentation

INTRODUCTION

Interest in the study of scientific argumentation in the classroom has substantially increased over the last decade. Moreover, studies in this area have become internationalized, as witnessed by the increase in the number of articles authored by researchers from various countries in scientific magazines published in English (LEE et al, 2009). The analysis of the argumentative discourse is considered one of the ways to access the elaborations of students on knowledge-related issues. These studies focus on the argumentation ability of the student and on the strategies used by teachers to foster this ability. However, only a few studies to date have addressed the means whereby scientists construct arguments in publications such as reports and academic articles. Still, we believe that the understanding of the properties of the scientific argument as used in scientific publications can contribute to research in science education, since the rational criteria underlying the production of scientific knowledge can be uncovered and, thereafter, best embodied in the development of the natural sciences curricula in schools.

This study is developed within this context, being aimed at investigating the nature of the scientific language in the scientific and the school contexts. We believe that by doing so it will be possible to ultimately assess of the nature of the knowledge retained by students during the process of learning.

METHODOLOGY

The analysis of the scientific arguments put forth in a scientific article is based on two original scientific articles (HERSHEY, CHASE, 1952; AVERY et al, 1944), which study the DNA as the carrier of hereditary information. Similarly, we analyze ten essays written by students in their last year of secondary school on the same subject. We used Toulmin's argument pattern (1958/2006) and the linguistic marks of Koch (2000) to identify elements of the arguments and their relations.

According to Toulmin (1958/2006), the step which authorizes the establishment of a *claim* (C) from any *data* (D) is called a *warrant* (W). *Warrant* is the information from which the argument is constructed, and which legitimizes a claim in the field of interest. However, the *warrant* is valid only under certain facts, observations, experiments, knowledge and laws by which they were established. It must have a *backing* (B) to make its formulation acceptable. It must also possess *modal qualifiers* (Q) – terms like *certainly, presumably, probably, necessarily* – that lend strength to the conclusions; and must have counter-arguments or *rebuttal* (R). When the conclusion is a simple statement of *data* and *warrant*, and does not present any new information, the argument is considered *analytic*. Conversely, when information between *data* and *warrant* are relevant, the argument is referred to as *substantive*.

The *linguistic marks* of Koch (2000) show the relationship between text and event and serve as clues to the reader, facilitating the comprehension of meaning. In this study, the following linguistic marks will be used to clarify the elements of arguments: tenses, modes of discourse, argumentative operators, relations between sentences and lexical selection.

RESULTS

The analysis of the texts showed that the students use mainly substantive arguments, whereas scientists make use of analytical arguments. The use of different tenses, both in the scientific discourse as in the texts produced by the students, reveals the transformation of functional biology into a historical narrative. Functional biology refers to phenomena or processes related to living organisms, such as genetic or behavioral responses, and answers to the question "How?", which is usually answered by studies in the fields of genetics, physiology, developmental and behavioral biology. Instead, evolutionary biology answers "Why?" questions, which relate to the understanding of the historical causes underlying the observed phenomena or process, namely those leading to new or modified genetic programs. Normally it is constructed as an historical narrative (Mayr, 2005).

Lexical selection and the use of qualifiers in the arguments set forth by both groups, students and scientists, revealed the shift from alethic modalities – which refers to the *truth* about a state of things or objects of thought – to epistemic modalities – those referring to *knowledge* of a state of affairs or object of thought. The epistemic modality appears only in the discussion of results in the writings of scientists. The analysis of their content shows that statements, conclusions and mainly questions requiring further testing can be only understood and verified by those working with science. When this scientific discourse is re-contextualized in a biology class, the alethic modality, used by scientists predominantly in the conclusions and presentation of results, is the modality used by students in their discourse.

DISCUSSION

The production of scientific knowledge occurs at different levels. Initially, scientific articles are produced, showing results for specific questions. For example, the article by Avery presented here shows that the substance responsible for changing transformations in bacteria is the DNA; and the article by Hershey-Chase concludes that DNA has a role in the reproduction of bacteriophage T2. In a second step, the scientific community relates these results to more general theories, in this case generalizing the function of DNA as the carrier of hereditary information in living beings. So for the lay public to have access to this general claim, their development and review within the scientific sphere were necessary. It is only after this hypothesis is scrutinized and tested by scientists that it escapes the boundaries of the scientific culture and undergoes re-contextualization into other spheres, such as education.

In the boundaries of school culture and science lay down scientific truths as known by the general public. The way a scientist access these truths is different from that used by students. To make a general claim, scientists delineate and implement scientific experiments and predominantly use analytical arguments in which data collection is valued; in those arguments there are implicit *warrants* and basic knowledge shared by the scientific community. The data collected might, only then, be considered as facts, from which deductions can be made.

In the classroom activity analyzed here, the teacher made general allegations and asked the students to justify them, making the *warrants* that justify the relationship between *data* and *conclusion* clear*;* in other words, they were asked to elaborate substantive arguments.

When one is part of a community, some of the assumptions connecting data and conclusions may not be tested and/or made explicit. However, at school, students are evaluated precisely by the understanding of these assumptions, so their explanation in an appropriate manner is required. The literature in science education emphasizes the development of substantive arguments by the students. Jiménez-Aleixandre and Díaz de Bustamante (2003), for example, perform their analysis only with those arguments considered substantial, or that require knowledge of the content and respond to problems posed in the classroom.

The existence of scientific "truths” in the zone of hybridization between the scientific and school cultures is associated with conceptions of science that take into account the process of building these truths, the notion that they may be provisional and subject to testing, the human and fallible nature of scientific knowledge and the degree of success in the explanation that is proposed. While these truths are expressed through the alethic modality, the view of science as transitory can be expressed by the epistemic modality. We verify in this analysis that the border zone between school culture and scientific culture reveals the use of both types of modalities, but with elements of each of them that are restricted to the practitioners of each sphere.

The analysis presented here suggests that the route taken by students to access scientific truths or construct conceptions of science involves stages and processes that are different from those employed by scientists. If, on the one hand, it is not sufficient for the purpose of science education to enable the understanding of results and conclusions produced within the scientific realm, on the other, not all rules are accessible to students. Thus, science education must be seen as a process of constructing an idiosyncratic view of science that involves the understanding of its concepts and language, not by adopting this new culture, but by interacting with it.

A COMPARATIVE STUDY OF THE SEMIOSIS PROCESS IN PHYSICS TEACHING

Gérard Sensevy[1] *and Andrée Tiberghien*[2]

[2] Unité Mixte de Recherche Interactions, Corpus, Apprentissages, Représentations, CNRS - Université Lyon 2 - ENS-Lyon, France

Abstract : This study is comparative, it aimed at achieving a better understanding of four features of the didactic semiosis i.e. the way teachers and students produce and recognize signs of various forms in order to teach and to learn: (1) The first feature is the semiotic systems that the teacher uses to represent different aspects of the knowledge at stake. The second one lies in the verbal discourse that enables the teacher and the students to acknowledge the same signs in a similar way. The third one refers to the actual didactic experience, in particular the bodily experience, in which the semiosis process takes place. The fourth one specifically focus on the way conceptual models of Physics in the classroom (the change of state of matter and the Inertia principle) are involved in the semiosis process. We present two teaching design experiments, at kindergarten, where we study the change of state of matter, and at 9th Grade, where we study the Inertia Principle. For each feature mentioned above, we present first an analysis focused on each level, then a comparison. We show how the teacher's and students' joint action relies on the semiosis process, through a dialectic relationship between the didactic contract and the didactic milieu.

Keyword: Semiosis, Joint action, Didactic resources, Design, Classroom

INTRODUCTION AND RATIONALE

We consider that discourse, argumentation, and epistemic practices take place within a semiosis process. The importance of semiosis has already be underlined in relation to an approach in terms of action and in strong relation to learning (Jewitt & al. 2001; Lemke, 2002; Kress, 2008). This semiotic process in science education takes place in the framework of school and classroom and we name it, the didactic semiosis that is the way teachers and students produce and recognize signs of various forms in order to teach and to learn. Four features characterize it. The first feature is the semiotic systems that the teacher uses to represent different aspects of the knowledge at stake. The second one lies in the verbal discourse that enables the teacher and the students to acknowledge the same signs in a similar way. The third one refers to the actual didactic experience, in particular the bodily experience, in which the semiosis process takes place. The fourth one specifically focuses on the way conceptual models of the taught discipline in the classroom are involved in the semiosis process. This last feature is specific of what is taught, in our case it is physics at two different levels, Kindergarten and grade 10. Thus refering to epistemological analysis, we argue that the didactic semiosis relies on various forms of representations, in Hacking's sense (Hacking, 1983). Such a system of representations plays a prominent role in elaborating a Physics *Thought Style* (Fleck, 1979) within the classroom (Sensevy, Tiberghien, et al., 2008). In this presentation, we use a comparative method in order to understand how the semiosis process unfolds in a systemic way at the two different school levels kindergarten and 10^{th} grade. This study is a first step of the research project.

METHODS

In both cases, the teaching sequence was designed by a group of researchers and teachers.
At kindergarten, the change of state matter: We focus on an exploratory research (Sensevy, 2010), in which the research team worked on the change of state matter at Kindergarten in a "lesson studies" design. The main conceptual goal of the study was students' understanding of what is permanent through the change of state matter. We used different semiotic systems, including a "paper thermometer", a diagram differentiating "liquid water" and "solid water", and a molecular representation of "liquid water" and "solid water", relating to verbal language.

At 9th grade, the Inertia Principle: We designed a teaching sequence on mechanics (grade 10) (Tiberghien et al., 2009) in which we first introduce the notion of action associated to a *diagram called system-interactions* where the object (or system) is represented by an ellipse, a contact action by a full double arrow, and a distant action by a dotted double arrow. Then the concept of force exerted by a system on another one with its vector representation is introduced before the Inertia principle. Thus the concepts and the experimental facts are clearly distinguished; the action is associated to the fact that an object is acting on another one and force is the concept that models this action.

Collected data

In both case studies, the main data are video recordings of the classrooms and two cameras were used. In Kindergarten, the team research implemented two successive versions of the same learning session. The teacher was a primary school teacher (and teachers educator) of the team. In mechanics, a grade 10 physics classroom was videotaped during the dynamic part of mechanics teaching (7 sessions); the teacher used the designed teaching sequence.

We do not develop our methodology of analysis, we just mention that our analysis is carried out at different levels, going from a micro level of gesture analysis to a more global levels *and* the reverse; that is "zooming" in and out (Lemke, 2001; Roth, 2001)

RESULTS

We present our results first at kindergarten and then at grade 10, to show how the specific resources designed in the respective teaching sequence presented above allow students constructing and sharing new meanings.

Kindergarten: A major stake of the teaching experiment was that the students had to be able to relate the different states of matter to the measurement of temperature. In order to do that, the research team designed a teaching sequence in which the habit of daily temperature measurement was grounded on a "paper thermometer" (figure 1). This artifact was used in order to allow the teacher to "reproduce" the real temperature measurement, and to analyze it, namely by using the "zero" point as a distinctive feature of this process. This device allowed the students substantive meaning making progress, for example in the mathematization of their experience of "cold" and "hot", through the negative and positive temperature. The teacher and the students need to acknowledge a common vocabulary in order to be able to characterize their experience and to draw joint inferences of the common background linked to this vocabulary. In the class discussion, the expression "liquid water" and "solid water" were used. The situated mastering of this distinction allowed an evolution from concrete meanings to conceptual understanding. In particular, the teaching design organized a specific relationship within a semiotic system representing on the same diagram a model of the paper thermometer in front of each state of mater. In doing so, the teacher institutionalized the link between the "relevant" terms and the "accurate" temperature measurements. In the refinement process in which the research team was involved from the implementation of the first version to the second version of the design experiment, we met the following difficulty. The students were confronted first to "liquid water", then to "solid water", without being directly confronted to the change process. The research team dealt with this issue, in designing a situation in which the students' bodily experience played a prominent role. The students hold ice cubes in their hands, in order to let these ices cubes melt. In doing that, the students directly experienced the fusion phenomenon from the "solid water" to the "liquid water".

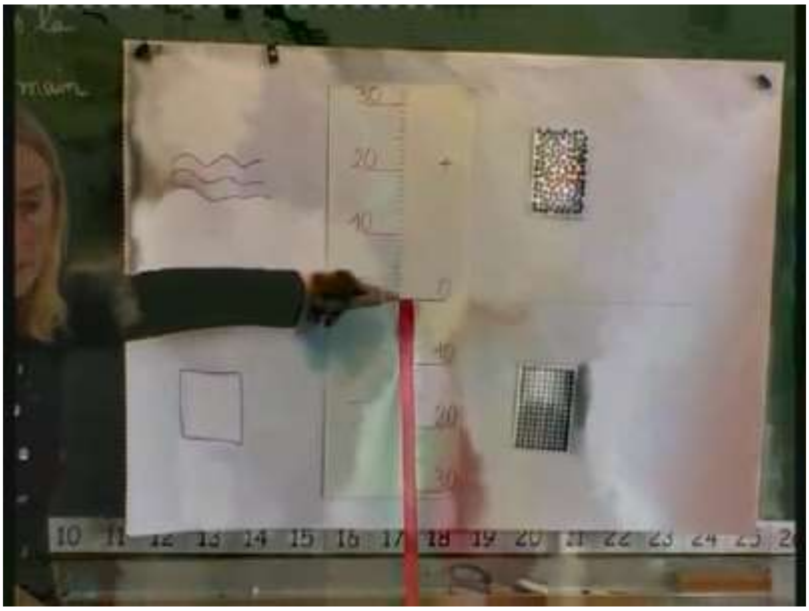

Figure 1: The paper thermometer (the red line can move according to the measured temperature)

At the end of the teaching process, in the first version of the design experiment, the team research noticed a lack of explanation for the phenomena of change of state of matter in students' verbal productions. The team research decided to ground the second version on a molecular model we presented to the students. This molecular model was added in a general "parallel diagram" in which was represented in an interrelated way i) the terms "liquid water" and "solid water", ii) the representation of the temperature measurement for each of these state mater, iii) the molecular model corresponding to "liquid water" and "solid water". This "complex" representational system allows the teacher and the students, in their joint action, to link verbal utterances, semiotic system, and conceptual model, by relying on memories of students' bodily "melting" experience. This system enables the teacher and the students to describe some parts of the system by using relevant utterances precisely relating to the diagram.

At Grade 10: A major stake of the first part of the teaching sequence was the notion of action in particular in motionless situation where no change is perceptible. This notion was associated to the system-interactions diagram that allows representing a variety of familiar situations where objects are motionless or moving in the same way. During this first part, some difficulties appeared, in particular the distinction between the action of the ground and that of the Earth. For example in the case of the actions exerted on a table on which a book is placed, whereas all students proposed the action of the book with a full arrow, a part of them proposed the distant action of the Earth (dotted double arrow) and the other part proposed the action of the ground (full double arrow) (figure 2). This difference in the diagram (full or dotted arrows) helped students to be aware of the differences between the two proposals and favours debates when students were working in small group and also at the whole class level with the teacher who fostered the debate. In these debates, the students understood each other easily to the extent that the rules of the diagram and the language associated were shared by all students; they mainly used verbs of action of the common language but they used the verb “to act” of which the meaning has been extended to situations where no change is perceptible (contrary to the everyday language).

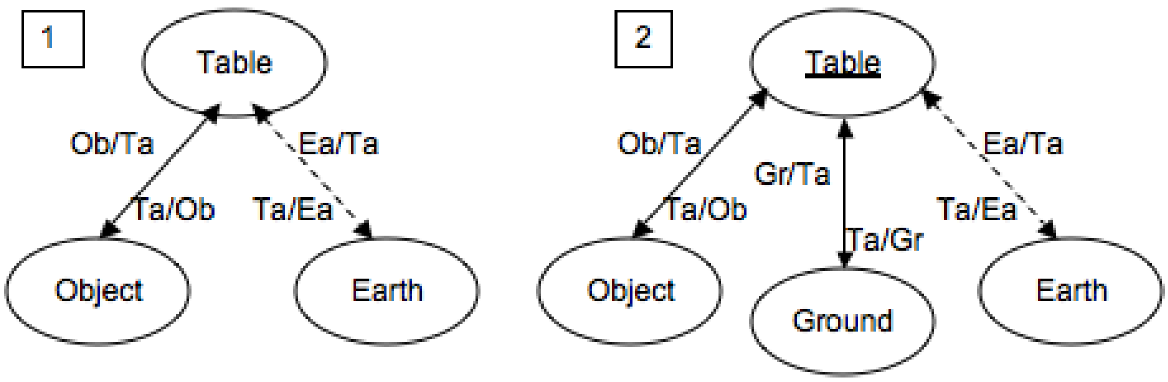

Figure 2 : part 1: student’s solution, part 2: correct solution

Most of the studied situations were very familiar to the students, but they required students to look at them and spoke about them differently. Just after these activities, the teacher introduced the direction of action with new activities where the students had to launch and received a medicine ball and thus had to perceive the direction of actions of their hands, in particular they had to differentiate the action of the hands and their motion when they received the ball. Here the reference to their bodily experience helped students to debate with an understanding of the various arguments. After these activities, the students were introduced to the concept of force including its vector representation. Force was exclusively used (at least by the teacher) as the concept and not to describe the effective actions of objects. In this teaching sequence, the distinction between the events and the concepts was clearly made in the verbal language and in the semiotic representations of the force vectors where the objects are represented by points, with no mixture between the drawings of the effective situations and the force schemas. This clear distinction between material situations and the physics model of force was made easier because of the introduction of the diagram system-interactions. This diagram is a didactic construction only; physicists do not use it. It is an intermediary between the abstract conceptualisation of force and its vector representation. Thus during this teaching sequence,

CONCLUSION: A COMPARATIVE DISCUSSION, FIRST ELEMENTS

The two design experiments may be analyzed as relying on the same way of considering representations. 1) Some semiotic systems are used as *public* representations (Hacking, 1983) in order to conceptually characterize some fundamental *differences* physicists make in order to understand the world (for example diagram system-interactions; diagram thermometer-solid water/liquid water). 2) These semiotic systems are not only used in themselves, but they function as parts of larger representational systems (for example diagram system-interactions was related to the force model; diagram thermometer-solid water/liquid water was related to the molecular model in a “parallel diagram”). 3) These representational systems organize a specific seeing-as (Wittgenstein, 1997), which is the main feature of a thought style (Fleck, 1979) (for example seeing action in a motionless situation; seeing the liquid water as the same matter composed with the same molecules as the solid water under different temperature conditions). 4) These representational systems institute some precise relationships between verbal language and semiotic system, and allow systematic correspondences between particular utterances and specific semiotic structures (for example verbal representations as “the Earth acts on the table” precisely relating to the dotted arrow; verbal representations as “when temperature is below zero, the water is solid water, the water molecules are very close each other”, etc. precisely relating to the parallel diagram). 5) These representational systems are worked up in an embodiment process which enables the students to achieve a bodily understanding of some dynamic aspects of the representational systems (for example the students’ medicine ball experience helps them to understand the direction of actions; the students’ melting experience helps them to understand what is permanent through the change of state matter). 6) These representational systems provide a common background which foster epistemic argumentation and discussion in the classroom. We draw a main implication of our research with respect to the design of teaching sequences in Physics that lies in the necessity to build representational systems grounded on *systematically related* verbal and semiotic representations, with the help of the students’ bodily experience of some scientific meanings. We argue that such a didactic semiosis process enables the students and the teacher, in their joint action, to share both a concrete and an abstract understanding of the models of Physics.

QUESTIONS IN SCIENCE TEXTBOOKS: DO THEY PROMPT STUDENTS' INQUIRY AND PROBLEM-BASED LEARNING?

Clara Vasconcelos[1,2]; Joana Torres, J.[1]; Luís Dourado.[3] and Laurinda Leite[3]

3Institutre of Education, University of Minho, Braga, Portugal

Abstract: Problem-based learning (PBL) is an inquiry-based learning approach that fosters the development of students' autonomy as learners, and enables them to develop life-long learning competences. Problems and their underlying questions are building blocks of PBL approaches. Thus, questioning in science classes and textbooks can foster the development of students' inquiry and problem-solving competences. As teachers' teaching practices seem to depend on textbooks, this study compares the way the three Physical and the three Natural Sciences most sold textbooks deal with questions when developing the Earth in Transformation curriculum theme. This analysis focuses on: localization and function of the questions; nature of the answers demanded; and cognitive level of the questions. Results reveal that: only Natural Sciences textbooks use questions in the opening of the theme and its units; Physical Sciences textbooks have larger numbers of questions than the Natural Sciences ones do, being most of them connecting and knowledge application questions; both subjects' textbooks are similar in what concerns using questions as section titles and giving explicit answers to questions; Physical Sciences textbooks have a much larger number of non-guided answer demanding questions; whatever the subject, the number of high-level thinking demanding questions is low. These findings indicate that most science textbook questions can hardly promote student's inquiry and PBL.

INTRODUCTION

School plays a major role in the formation of the individuals' personality, making them more responsible, better informed and more critical while ensuring that they will be able to use knowledge adequately. Studies indicate that it is impossible to ensure scientific literacy using traditional methods. As such, it is very important that the process of learning science becomes increasingly meaningful, relevant and interesting. It is equally imperative that students become more active participants.

Questioning is considered to be fundamental to the learning process as it encourages students to find solutions to different problems. One of the most important objectives of formal education is to develop students' autonomy as learners.Thus, it is important to understand the best ways to encourage and promote questioning by students.This requires high-level thinking as well as learning how to develop competences. Solving problems and answering to high level questions may foster the development of those competences (Wragg & Brown, 2001).

Problem based learning is an inquiry-based learning approach where problems play a major role acting as a stimulus for students' learning. This method uses daily problems as a point of departure for the learning process (Lambros, 2004). The problem is introduced at the beginning of the unit of study, ensuring that students know what they are learning and why they are learning it, thus increasing their motivation. In this way, all information gathered by students is learnt with the purpose of solving a problem (Chin & Chia, 2004). According to this method, the learning process begins with the identification of the problem itself. Students are confronted with a scenario generally related with the real world. The latter promotes debate among students as well as they resolve to discover something relevant to their personal daily lives. Students formulate questions that help to diagnose their knowledge and their difficulties. Through this process, students learn to identify their prior knowledge about a subject, their related learning needs, and the best way to solve the problem and achieve relevant knowledge on the subject (Dahlgren & Öberg, 2001; Chin & Chia, 2004). In an inquiry-based learning approach, students should question, examine books and other sources of information, propose hypotheses, analyse data, propose conclusions and communicate the results. As De Boer (2004) says, although students achieve different independence levels within this approach, students are indulged to develop their problem-solving capability, preparing them to be self-oriented and concerned citizens.

Questioning, either in science classes or in textbooks, can work as a privileged strategy for students to develop PBL competences. However, not all questions are useful for this purpose. In fact, only questions that require understanding and high order thinking can be useful within a PBL framework. Science textbooks include questions with different characteristics and purposes when they develop content topics.

Although the Portuguese Educational System Law (law number 49/2005, 30 August) advocates science textbooks as an important educational resource, research has shown that textbooks are conservative with regard to the way they develop curriculum themes, forgetting problems and questions as important ways to promote cognitive development (Leite et al., 2011).

As teachers' teaching practices seem to be dependent on textbooks, this research study compares the way the three Physical and the three Natural Sciences most sold textbooks deal with questions when developing the Earth in Transformation curriculum theme. Results may help teachers and teacher educators to become aware of the potential of textbooks as inquiry promoting tools within the scope of PBL and to find out ways of overcoming their limitations, if necessary.

Questioning

For Dewey (1933), a question is a way to evoke, to provoke or encourage inquiry.

A question may be conceptualized as an issue put forwards for discussion in such a way that it demands an answer. Hence, questions are associated with problems, as both include a sort of obstacle that needs to be overcome by the respondent or problem solver.

The formulation of questions is a frequent activity in our daily lives and also in the classroom. In the context of the classroom, the question is particularly important and even considered the essence of the learning process. It creates imbalances that encourage students to seek for new solutions (Giordan & Vecchi, 1996).

To accomplish their role as curriculum development mediators, school textbooks should foster the development of students' questioning and problem-solving abilities. There is some evidence that Portuguese school science textbooks include many questions, even though some of them cannot be associated to problems, as they do not require, at least, comprehension of the science issues (Dourado & Leite, 2010). Assuming that questions may be the start of a meaningful discourse, textbooks should use questions as a starting point for developing the curriculum theme, and its teaching units, sub-units or sections, in order to foster students' cognitive and affective engagement with the issues to be addressed. Some textbooks do this more often than others but when they do it a few of those questions are left unanswered (Dourado & Leite, 2010).

Questioning has concentrated many researchers' attention and has been investigated from diverse angles, including questioning in the classroom, teachers' questions, students' questions, textbooks questioning, etc. Literature (Wragg & Brown, 2001) indicates that: teachers ask too many questions, and that most of them are not only low level questions but also questions that are not supposed to be answered by the students; students are not used to be asked to formulate questions but when they have the opportunity to do so, they do it very satisfactorily. However, the cognitive level of students' generated questions seems to depend on the characteristics of the problem context that elicits them (Dalghren & Öberg, 2001).

Several question taxonomies emerged from research undertaken. Some of them draw heavily on the cognitive requirements of the questions and follow Bloom's Taxonomy of educational objectives; others pay some attention to procedural competences and therefore combine cognitive-based and procedural-based categories; others include also value-laden categories. Dalghren & Öberg (2001) defined a taxonomy of students' formulated questions that follows the latter pattern. It includes five categories as follows: Encyclopaedic Questions, demand an unambiguous and not complex answer (e.g., What is a fossil?); Meaning-Oriented Questions, oriented towards finding a phenomenological meaning of certain terms or concepts (e.g., How can the study of meteorites help to understand the structure of the Earth?); Relational Questions, focus on relationship between aspects/ features (e.g., What is the relationship between the different types of rocks?); Value-Orientated Questions, demand for a judgment based on some criteria (e.g., To what extent is nuclear energy a safe alternative to fulfil the world energy needs?); Solution-Oriented Questions, focus on looking for solution(s) for a problem (e.g., Write an essay on the energy crises focusing on what can be done in order to reduce the excessive use of fossil combustibles and the energy crises).

METHODS

To attain the objective of this study, the three Physical (PS) and the three Natural (NS) Sciences most sold (in 2010/2011) textbooks dealing with the Earth in Transformation curriculum theme were content analysed. The analysis was based on a checklist based on Dahlgren & Öberg (2001) and Dourado & Leite (2010)). The analysis focused on the questions included in the selected textbooks but excluded questions given within learning activities (e.g., questions on data analysis of a given lab activity included within the lab worksheet). Data collection was done by two of the authors, after a deep discussion of the checklist. Due to space restrictions, quantitative results will be presented per subject only.

RESULTS

Physical Sciences textbooks include a larger number of questions than the Natural Sciences ones (table 1: PST- 403; NST- 135), due to their large number of application questions (242).

As shown by table 1, Natural Sciences textbooks present questions when opening the theme or its units. This is consistent with a PBL approach. Whatever the subject, textbooks use questions as section titles and to guide students with regard to expected learning results. This is consistent with an inquiry perspective and relevant for guiding students through the sections too. As far as the nature of the answer demand is concerned, the two groups of textbooks are similar except in that the Physical Sciences ones give guidance to students to answer to a large number (272) questions and Natural Sciences do not.

Table 1. Number of questions per dimension, category and subject

Dimensions of analysis	Categories | sub-categories		NST (n=135)	PST (n=403)	Total (538)
Localization of the question	Opening of the theme		9	0	9
	Opening of Units		31	0	31
	Title of sub-units		0	27	27
	Title of sections		49	36	85
	Throughout a sub-unit or section text	Integrated into the content being presented	5	39	44
		After the content presentation	1	242	243
		Resolved questions	0	12	12
		Other	2	0	2
	Associated to learning activities	Activities title	30	1	31
		Activities statement	8	30	38
	End of the sub-unit or section		0	16	16
Function of the question	Present expected learning results		40	27	67
	Present the text to be developed		3	36	39
	Link parts of a text on a given issue		53	39	92
	Present learning activities	Explicitly optional activities	2	0	2
		Explicitly compulsory activities	34	31	65
	State knowledge application activities	Explicitly optional activities	1	16	17
		Explicitly compulsory activities	0	242	242
	Illustrate problem solving processes		0	12	12
	Try to keep readers' attention		2	0	2
Nature of the answer demand	Answer ignored		4	9	13
	Answer given	Explicitly	118	122	240
		Implicitly	8	0	8
	Answer required to students	Without guidance	0	0	0
		With some guidance	5	272	277

It should also be emphasised that, whatever the localization of the questions, the cognitive requirements for giving a successful answer to most of them are very low, as most questions are encyclopaedic (table 2). Relational, value-oriented and solution-oriented questions were hardly found.

Table 2. Cognitive level of the questions according to their localization in the textbooks (f)

Localization of the questions	Types of questions									
	Encyclopaedic		Meaning-		Relational		Value-oriented		Solution-	
	NST	PST	NST	PST	NST	PST	NST	PST	NST	PST
A	9	0	0	0	0	0	0	0	0	0
B	16	0	9	0	5	0	1	0	0	0
C	0	11	0	16	0	0	0	0	0	0
D	43	16	4	20	1	0	1	0	0	0
E	1	25	3	14	1	0	0	0	0	0
F	0	184	0	57	1	0	0	0	0	1
G	21	0	5	1	2	0	2	0	0	0
H	0	14	0	15	1	0	7	0	0	1
I	0	5	0	11	0	0	0	0	0	0

Legend- A: Title of the theme; B: Title of the unit: C: Title of the sub-unit; D: Title of the sections; E: throughout a sub-unit or section text (integrated into a text being presented); F: throughout a sub-unit or section text (after content presentation); G: associated to learning activities (activity title); H: associated to learning activities (activity statement); I: end of sub-unit or section.

This result may be due to the fact that traditionally textbooks in Portugal don't include many problems or questions for students to solve or to see how they can be solved. In addition, the Portuguese curriculum is not a Problem-Based Curriculum, fact that does not help teachers to embrace problem solving or demand students to question.

CONCLUSIONS AND IMPLICATIONS

Physical Sciences and Natural Sciences textbooks differ in what concerns the number of questions they include as well as with regard to the way they use the questions. Although both groups of textbooks seem to acknowledge an inquiry based approach, Natural Sciences textbooks seem more consistent with a PBL approach as they use questions as the starting point for developing the theme and its units. On the other hand, even in Natural Science textbooks, most of the questions are encyclopaedic demanding a low cognitive level to give a correct answer. However, research is needed in order to find out how the textbook authors deal with those opening questions, especially in terms of what is supposed to be done and by whom to answer them. To analyse the answers given to these questions is a relevant issue for a deeper judgement of the potential of textbooks as PBL promoters.

Note: This research was carried out within the scope of the Research Project "Science Education for Citizenship Through Problem-Based Learning" (PTDC/CPE-CED/108197/2008), funded by FCT within the scope of the Thematic Operational Programme Competitivity Factors (COMPETE) of the European Union Community Support Framework III co-funded by the European Regional Development Fund (ERDF/FEDER).

DISCOURSE IN SCIENCE TEACHER EDUCATION: A METHODOLOGICAL APPROACH TO SEGMENT DISCOURSE IN LEVELS [1]

Rodrigo Drumond Vieira[1] *and Silvania Sousa do Nascimento*[2]
[1]FAE/UFMG/Brazil
[2]FAE/UFMG/Brazil

Abstract: In this paper we address the problem of methods of discourse segmentation, for discourse analysis, in science classrooms. Due to the specificities of the context of science teacher education, we argue for the development of specific methodologies to analyse discourse in these contexts. Thus, in this paper we describe a method that our research group has developed to segment science teacher classroom discourse in levels, adapted from Leont´ev's (1978) structure for human activity. This approach offers space for an iterative and reflective process of inquiry. Also, our method is grounded in sociolinguistic features such as contextualisation cues, which allows us to inquire from an emic perspective. In this sense, segmentation can be recognised by participants ("insiders"). From the structure of the activity proposed by Leont´ev, we derived the respective levels for discourse analysis (activity, action and operations levels) and we introduce the episode level between the activity and the action levels. We discuss why we introduced this additional level. We also present a whole schema to illustrate our method of segmentation for a selected analysis, which we made from a physics teacher education course. Finally, we discuss the status of this approach within the research field.

Keywords: Science teacher education; Discourse segmentation; Levels of analysis; Activity theory.

INTRODUCTION

Classroom discourse analysis is nowadays a consolidated field of research (Kelly, 2007). Although there is a substantial body of literature regarding discourse in basic science classrooms, relatively little research has been conducted into science teacher education. We suggest that methodologies to inquire into discourse in science teacher education contexts are needed, due to the specificities of such contexts. In this paper, we will present a method for segment discourse in the context of physics teacher education.

We consider it important that discourse analysis should be done at different levels, each one related to one type of discourse segmentation. This is justified by our consideration that discourse mapping at different levels is a relevant methodological approach to provide a basis for analysts to make inferences and interpretations informed by contextual feedback and sociolinguistic cues of different natures (e.g. Castanheira et. al, 2001). However, the traditional approach is mainly based on a time-scale criteria for discourse segmentation. As an alternative, our proposed approach deals with discourse segmentation from a psychological basis – Activity theory

Corresponding to such a perspective, our research group has focused on understanding the emergence of Discursive Didactic Procedures (DDPs) in the discourse in science teacher education contexts. Activity theory (Leont´ev, 1978) plays an important role to present and understand the DDPs from a situated perspective. From activity theory we developed a method to map discourse through segmentation at different levels. Each level is related to the others in an iterative and reflective process of inquiry. This method will be presented in the next section.

METHOD TO SEGMENT SCIENCE CLASSROOM DISCOURSE INTO LEVELS

Our method emerged from data gathered in a preservice physics teacher education course. The data is composed of 44 hours of audio and video recordings. Field notes were taken, and two interviews with the course teacher (hereinafter called "Teacher") were made: the first before the course began, and the second after it concluded.

In order to develop the discourse segmentation, we adapted the concept of units of analysis of one activity as proposed by Leont´ev (1978). Our choice is justified by the structural character of human activity that his proposal represents.

According to Leont´ev, any human activity can be analysed from different units: activity (related to a motive/need), action (related to the achievement of a conscious goal), and operation (related to conditions and methods of action accomplishment). For classroom analysis, we adapted this model to develop the levels of analysis (activity, action and operation levels) and added, between the activity and the action level, the level of "episode" (related to a common theme and to a chain of actions in which we can identify a temporal and logical sequence of beginning, middle and ending phases). The episode is not mandatory, because there is not always a thematic sequence of actions with beginning, middle and ending phases. The other levels are mandatory.

For each level, we have different criteria to determine a specific discourse segment. We will present these criteria briefly in the next sections, focusing on Teacher´s discourse.

Activity level (mandatory) – motive/need/main goal

Through readings from field notes, the analyst infers for each class a motive that emerges from Teacher´s need. The motive is an object (ideal or material) that fills one´s need, and that is a determinant for the activity level. Due to the fact that field notes can be read in a few minutes, this gives us a broad perspective of the events accomplished in one class. Thus, we chose to make inferences regarding activity (need, motive and a main goal) relying mainly on cues from field notes. Also, we defined one activity as one whole class.

Thus, with this information, we constructed a "Class Presentation Frame". Due to space restrictions, it is impossible to present any stretch of such frame here (and from other frames that will be mentioned later). For this, we refer readers to another work (authors, in press).

Action level (mandatory) – pragmatic goal

At this level, the analyst must define one main pragmatic goal for each action. The question that arises is: how can we segment the actions? Due to difficulties in distinguishing one segment from one goal, we chose to define the segment first and then assign one goal to it.

We made the decision to segment actions based mainly on contextualisation cues, a central concept of the sociolinguistic approach (Gumperz, 1982). This approach seeks to understand interactions and discursive meanings from an emic perspective (i.e., through the participants´

perspectives). The video was our primary reference for describing the boundaries of actions through contextualisation cues. Such cues mark redundantly changes in the content of speech, and changes in the flow of discourse. We call these delimited actions “clips”.

With such orientations in mind we constructed the “Narrations Frame” (authors, in press); and, we assigned modes of language organisation to each clip, which we call “discursive orientations”. This concept is adapted from literature on textual linguistics and text grammar (we recognise six types of discursive orientations relevant to science classroom discourse: argumentation, explication, description, narration, injunction and dialogue, see Adam, 1992; Werlich, 1976). Then, we made narrations of the ongoing discursive interactions for each clip. At this time, the analyst seeks to be more impartial. After this procedure, and through reading the narrations for each clip, a name is assigned to each clip in separate a column. The name represents an abstract for the particular clip and describes its main action. The analyst writes comments in the same column, and at this time the analyst can be more partial.

Based on the clip´s name and its narrations, the analyst assigns one teacher´s pragmatic goal for each clip in another column. In other work (authors, in press) we give more information about this pragmatic approach for deriving goals.

Operation Level (mandatory) – conditions and methods

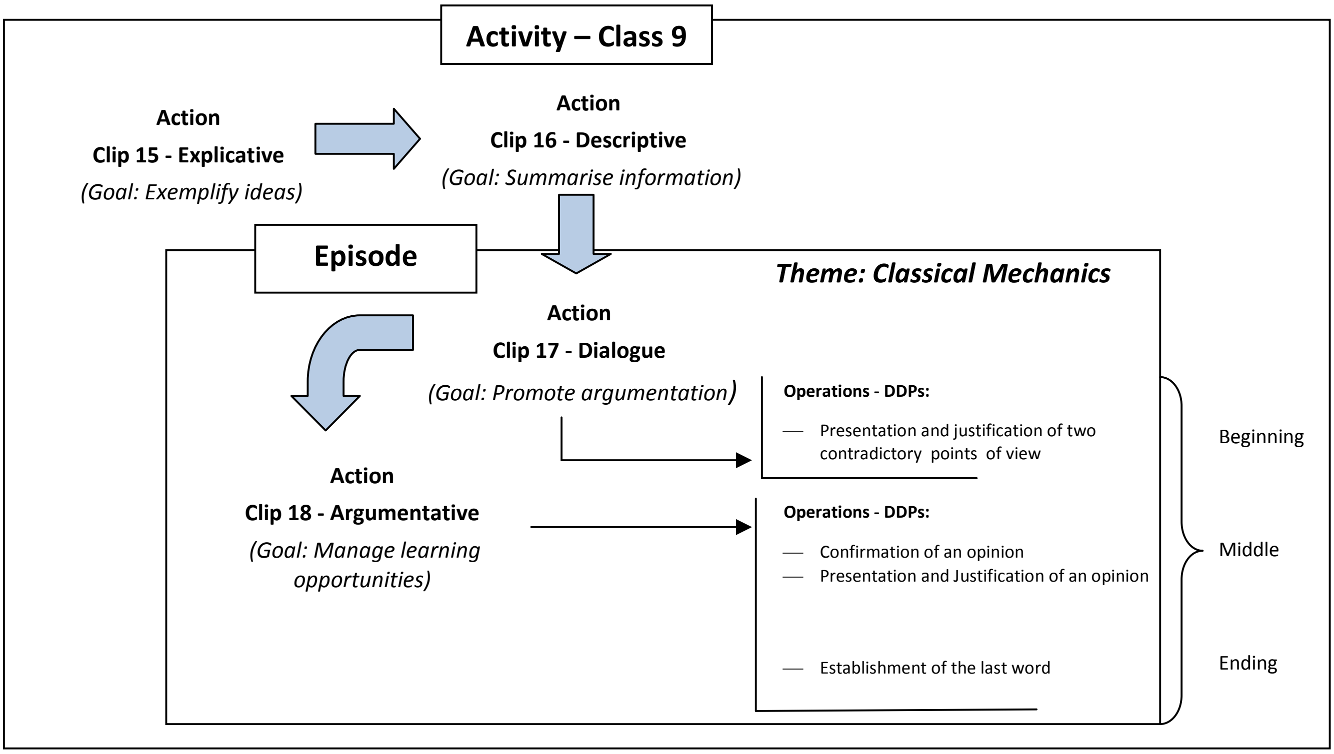
This level is related to the moment-by-moment interactions among participants. Operations are usually automatic and seek to satisfy the action goal to which they are linked.

It is at this level that we derive the DDPs, which are constituted by propositions (which are smaller units of meaning that can be identified in discourse). Again, such categorisation can be found in another work (authors, in press). The analysis process is taken into consideration to contextualisation cues, which are the main criteria for identifying the propositions. This process allows us to inquire from an emic perspective, because it is based on sociolinguistic criteria.

Episode Level (optional) – set of actions with a common theme and composing a whole with beginning, middle and ending phases

We added this level to the structure we adapted from Leont´ev. This level is situated between the levels of activity and action. Our choice is based on the assumptions that science classroom discourse is episodic by nature (Lemke, 1990), and that one action (clip) does not always constitute an episode. Dominant thematic content is central to this definition of episode. Also, our definition of episode requires the presence of a logical structure of beginning, middle and ending phases. Figure 01 illustrates these points: a class (activity), the clips (actions), some DDPs (operations) and the episode as the sum of dialogue and argumentative clips.

Figure 01: Representations of levels of analysis for class 9



DISCUSSION

Our proposal of the levels of analysis stands out because it is based on a psychological theory of human development – activity theory – and its adaptation to the specific context of science teacher education. In this sense, our approach is informed by, but also can inform, an activity theory perspective of human learning and development.

We consider that the process of analysis in levels is fundamental to an understanding of the "discursive rhythm" in science classrooms. In this approach, each level offers context and feedback with which we can understand the next levels. In addition, it offers interpretative cues and criteria for the selection of new events to be analysed. Finally, we consider that only future research that uses and makes adaptations of our proposed method of discourse segmentation in levels will be able to authenticate its flexibility and validation.

PART 7: SCIENTIFIC LITERACY AND SOCIO SCIENTIFIC ISSUES

<u>*Co-editors:*</u> *Virginie Albe and Bob Evans*

Teaching about scientific literacy, science and citizenship education, science and media education, information literacy, informal reasoning and critical thinking, decision making, debates on socioscientific issues (SSI), discourse communities, social dimension of science and technoscientific practices, public engagement in science, schools', students' and teachers' engagement in socioscientific issues.

This part corresponds to strand 7. It contains 20 papers.

TABLE OF CONTENTS OF PART 7

SCIENTIFIC LITERACY AND SOCIO SCIENTIFIC ISSUES

INTRODUCTION

Research presented in this strand were dedicated to students' and teachers' attitudes towards science, technology, socioscientific issues or scientific literacy, discussions and /or decision making on SSI, school practices and science teaching on SSI, students' and teachers' reading of science stories, media and Internet. The articulation of media literacy to science education and the contribution of science education to citizenship education are then major issues addressed in the researches presented in this strand at ESERA 2011.

University students' decision-making on an environmental problem was investigated (Uksola, Maguregi & Jiménez-Aleixandre, 2011). Students had to select a heating system for a future building from among five possibilities. Decisions were made by students in reference to a normative framework adapted from Janis and Mann (1977). Students demonstrated their willingness to consider the advantages and disadvantages of the alternatives and their requirement of having information available before making a decision. Secondary school students' decision making on a friendly-environment energy were also studied within the implementation of a teaching unit on photovoltaic that included explicit decision making training (Knittel and Mikelskis-Seifert, 2011). Results showed a highly significant increase of students' knowledge and three main categories of decision making were identified. Students based their decisions on (1) intuition, (2) a cut-off or a list of benefits or (3) a trade-off. Evaluation strategies and content knowledge were also identified as playing a major role in secondary school students evaluation and judgment competence in chemistry (Hostenbach and Walpuski, 2011).
Ecological-oriented arguments were the less used by 13-14 years old students when expressing their decisions about the reintroduction of Bears in the Pyrenees (Domènech and Márquez, 2011). Students developed, on average, only one argument to justify their opinion, with a moral base or, more frequently a social base, with either a focus on humans or a focus on bears. Most of the secondary school students' implied in another study focused on three socio-scientific issues (energy crisis, global warming, water taxation) lacked scientific knowledge and considered the issues not as technical but as ethical problems (Mercan, Yakmacı-Güzel and Akarsu, 2011). SSI dilemmas, are apprehended by students as having their roots in human nature, manifested by the actions of individuals and governments. Students viewed human nature as extremely individualistic and highlighted the need for regulation by a higher political authority but do not feel confident on individuals and governments in their efforts related to SSI. Students felt doubt and despair about the possibility of solving the SSI dilemmas. Students' views on actions required towards the SSIs showed that while aware of political dimensions of the issues, and opened to taking pro-environmental actions, students do not considered themselves as active agents.
Science and mathematics teachers involved in a risk-based decision-making scenario related to surgery which includes elements of probability and outcomes tended to trust medical/scientific authority even though they acknowledge the uncertainties associated with this source of data (Levinson, Kent, Pratt, Yogui and Kapadia, 2011). Teachers decision-making process was justified with evidence-based reasoning but their decisions did not necessarily follow from reasons given. Teachers' explicated their personal models of risk which incorporated both rational assessments and values based considerations at a personal, experiential and social level.
Higher education French and Australian students discussions on a digital platform on environmental socioscientific issues for sustainability were studied (Morin, Simonneaux, Tyltler, Simonneaux, 2011). Three issues were submitted to students : a green algae outbreak along the coast of French Brittany linked to release of fertilizers, the construction of desalination plants to produce fresh water in Australia and consumption of meat. Types of discourse were identified within Mercer (1995, 2002) analytical framework : disputational talk, cumulative talk, exploratory talk and

domains of validity of arguments were identified in reference to Habermas (1987) worlds : objective world, social world, subjective world. Results showed a lot of cumulative talks. Morin et al. (2011) argued that the digital platform both support and constrain students' discussions, "with a lack of dispute in forums and wikis, and the problem of distribution of responsibility on the one hand, and with the value of the international forum in creating the requisite disturbance on the positive side."

Primary school students' attitudes towards technology were also investigated (Mıhladız, Duran and Yıldırım, 2011). Results showed no significant difference between students' attitude scores in terms of gender. Significant differences were found in students' attitude scores in terms of students' schools, grade levels and their families' income levels. Differences identified in attitude scores of students were found in favor of 6th grade students, the children of middle-level income families, and students of the schools close to the middle-level socio-economic levels.

In another study, high school students prior knowledge about mass extinctions and loss of biodiversity was identified (Almeida, Vasconcelos and Torres, 2011). Science and literature students showed knowledge they gained from generalist media (TV, Internet and Press). Science students showed a better perception of the catastrophic way that extinctions took place and a higher coherence in the selection of the causes of these extinctions. Students showed major difficulties in locating extinctions correctly in a geological scale time with science students achieving higher results. Students identification of endangered species were very similar between the science and literature students, showing that some students hold wrong information.

Media literacy is an aim that is articulated to scientific literacy in several works.

One approach is based on the idea that science fiction could offer significant contributions (Stavrou & Skordoulis, 2011) to improve the capacity to reflexively assess new and emerging technologies and the social dynamics of socio-technical systems (Miller & Bennett, 2008). Research was conducted with primary school students examining whether they can identify the issues raised by the ethics, moral and political aspects of Technology (Nuclear Technology, Biotechnology, Information Technology and Computer Technology) through analysing science fiction texts (short stories). Results show that students can identify the elements of the texts referring to the positive and negative aspects of technology concerning the ethical and moral issues related to society. The majority of students mentioned the 'dual use' of technology. In addition, they associated the use of technology to matters of politics and power, even when the text dealt with subjects the students were not familiar with. In addition, students were at ease writing science fiction stories of their own. In their writings, students raised societal, ethical and moral aspects of technology especially, as far as the use of technology as a solution to environmental or health problems is concerned (the hole in the ozone layer, cleaning the polluted seas, medication for the poor).

Another study focused on how a module on scientific and media literacy can initiate student–teachers' thinking and actions to handle media science information, to get familiar with current knowledge and debates and to produce teaching material about a new scientifically contemporary topic, the stem cells (Spiliotopoulou and Papantoniou, 2011). Future primary teachers searched and selected media material in order to get informed about the topic of stem cells. The further goal was to develop awareness on the stem cell issues in order to build a teaching unit about stem cells for primary students of 6th grade. Results showed that the controversies documented by the future teachers were related mainly to socio-ethical issues on private stem cell banking, while the issue of ethics concerning embryonic stem cell use was almost absent.

Findings showed that student-teachers accessed a substantial number of media, mainly electronic sources. The public domain of science as portrayed in student-teachers' collected material seems to affect the kind of thinking they develop and also their teaching plans. Private stem cell banks' sites seem to be a major source of information for student-teachers, though few sources can be considered reliable. Their awareness of socio-scientific issues of this nature needs further development and evidence suggests that there is a need for more specific guidance to be included in the teacher education course activities.

The critical reading of two newspaper articles with scientific content by students aged 15 to 16 was also assessed (Oliveras, Márquez & Sanmartí, 2011). The newspaper articles dealt with the difficulty involved in removing graffiti on glass and the opinions for and against whether the swimsuits used by swimmers had helped improve the latest Olympic records. Results showed that identifying the writer's purpose and identifying data and evidence given in the text were tasks students found the most difficult overall. These results were interpreted in relation to students representations of the media. Students were mostly convinced that the purpose of the text was to inform and that this information is always neutral and unbiased.

Research also focused on the potentialities of a socio-critical and problem-oriented approach to science teaching as a basis for learning about assessing information (Eilks, Marks and Burmeister, 2011).

Teachers conceptions of scientific literacy, of values related to scientific literacy and viewpoints on SSI implementation in class were also studied. It is apparent that secondary school science teachers read and interpret curriculum in ways that match their value set (Cooper and Corrigan, 2011). This influences their notion of scientific literacy and their teaching practice with a great coherence with their underpinning values.

Some difficulties in the implementation of SSI activities by pre-service physics teachers were identified (Bernardo, 2011). Lack of time and lack of flexibility of school programs were mentioned. The teachers' training and the interdisciplinary nature of the SSI perspective have also been identified as constraints for implementing SSI in class. Teachers indicated the role of SSI in catalyzing discussions hat promote the exercise of dialogue and argumentation by the students. However, results also revealed a tendency to prioritize actions in the classrooms that reinforced the development of arguments conveyed mainly through media or experts. A focus on communication raises the question of an potential effective contribution to a critical education of students.

How middle school teachers from various subject matters negotiate with SSI themes and contribute to citizenship education was also investigated (Barrué & Albe, 2011). Results showed a tension between a contribution to a citizenship education that focuses on civility and rules and a critical emancipatory citizenship education. The latter corresponds to the aim to develop pupils' skills such as searching and evaluating information, developing argumentation and critical thinking in order to be prepare pupils to build their own argued opinion and participation to public debates.

Interrogations were then also focused on understanding how science education may contribute to scientific literacy and citizenship education or civil society (Geiger, 2011). Participative democracy is an aim often called within the SSI movement and advocated in science education reforms at an international scale, but more research efforts are needed to document the potentialities or constraints of scientific literacy and citizenship education through science curricula.

Virginie ALBE & Robert EVANS

MASS EXTINCTIONS AND LOSS OF BIODIVERSITY: PRIOR KNOWLEDGE IN SCIENCE AND LITERATURE HIGH SCHOOL STUDENTS

António Almeida[1,2]; Clara Vasconcelos[1,3] and Joana Torres[1]
[1]Center of Geology of Oporto University, Portugal
[2]Higher School of Education, Lisbon, Portugal
[3]Faculty of Sciences, Oporto University, Portugal

Abstract: The now ending International Year of Biodiversity put the issues of mass extinctions and the loss of biodiversity in the media agenda. Being aware that this issue is only addressed superficially in the Portuguese science curricula, the authors assess the related prior knowledge held by science and literature high school students. Indeed, several studies mention a relationship between science‟s prior knowledge and the choice of a science or literature course. So, a questionnaire was applied to 404 students of 12 classes from 6 schools from Lisbon and Oporto (Portugal) that included questions regarding the groups and the species that became extinct throughout the history of the Earth, the causes of these extinctions and the main informal sources available for gathering this information. All students revealed some knowledge on this issue. Science students showed a better perception of the catastrophic way that extinctions took place as well as of their causes. Regarding informal sources of information on this subject, the majority of students in both groups chose the generalist media (TV, Internet and Press) as primary source. More specific sources of science information, like science centres, scientific magazines or books, were less selected. In this study, there is no clear relation between prior knowledge and career choice, as results give evidence that prior knowledge is similar in science students and literature students. However, students‟ interest in science is one of the main reasons for choosing a science course. Authors claim that including this issue in school curriculum can develop students competence, as well as their attitudes concerning environmental problems.

Keywords: mass extinctions, loss of biodiversity; science high school students; literature high school students, prior knowledge.

INTRODUCTION

It is expected for science students to have a better scientific literacy than literature students, as they study science in school. Furthermore, it is supposed that their interest towards science may lead them to search for information, either in formal or in informal contexts of learning. In fact, as Masnick et al. (2010) indicated, “Interest in a subject leads to the acquisition of knowledge in that domain, which leads to competence in the tasks in that area, which in turns feeds continued interest” (p.653). However, several studies suggest that students‟ attitudes towards science decreases over time (Masnick et al., 2010*)*. Indeed, the ROSE international project states that there is a negative correlation between students' interest in science (currently low) and science test scores (often high). The ROSE project has shown this evidence when presenting the correlation of -0.92 in the answers given by students from over 20 countries stating that "I like the discipline of science more than any other discipline". Moreover, according to the Human Development Index, the more developed a country is, the fewer youngsters show interest in science (Sjøberg & Schreiner, 2005). On the other hand, literature refers to the importance of foster students towards scientific professions and mentions the importance of making students identify with practitioners in science fields (Masnick et al., 2010). It seems that some factors, (such as reduced competence in science) lie behind students (particularly women) deciding against a course and a career in science.

However, other reasons as social factors, decreasing feelings of competence in math and demotivating science classes may interfere with students‟ choice. Grazzia et al. (2011) mentioned that the interest in science is not only important as a precondition for successful learning, but has a major influence on students‟ choice for the field of study. The same authors also refer to the fact that science is often linked to enjoyment and personal value, which remind us the importance of the popularization of science and the enormous contributions of informal places to initiate students to have interest in science. Learning science in informal environments has grown rapidly in extension and diversity and informal education has acquired increasing importance as an element of promoting activities which enhance the public understanding of science and also as a complement to formal learning. A distinction is frequently made between formal learning (which might occur in the formal setting of schools) and informal learning (which could occur in informal environments) (Anderson, Lucas & Ginns, 2003). Prior knowledge is generally acquired in out-of-school learning experiences such as museums visits, field trips, zoos, aquariums, nature centres or other informal settings. Although the growing body of research on learning in such free choice situations is increasing, there is a clear lack of learning studies from film, radio, community-based organisations such as scouts, summer camps, home, friends, the workplace, the Internet and a whole range of other real-world situations (Dierking et al., 2003). On the other hand, some authors claim that learning may continue well past the time span of a learning experience in an informal context. (Anderson, Lucas, Ginns & Dierking, 2000; Rennie & McClafferty, 1996). Hence, even in school settings, students are frequently exposed to learning in informal contexts, such as field trips or planned visits to other learning institutions. This idea emphasizes the importance of prior knowledge in the process of developing scientific literacy, increasing the attention of educators and curriculum designers. The question is to what extent prior scientific knowledge (acquired spontaneously in informal contexts) and the inherent scientific literacy may have a role in an important decision such as educational and career vocational choices. It seems that the more we know about a subject, the more literate and competent we are and the more interested we will be in studying it more. The experiences students have in daily situations dynamically interact to influence the ways they construct not only scientific knowledge and understanding but also attitudes and behaviours. The fact is that if students do not enjoy studying science, then they do not choose scientific careers. This lack of attention regarding this item may be an aspect to consider when trying to promote the students‟ choices for scientific professions. Prior to any formal instruction, students have a great deal of experience that is relevant to the development of a very substantial body of knowledge (Sherin, 2005), helping students to learn within formal settings and possibly influencing their consequent scientific vocational choice. As so, Science‟s prior knowledge may play a decisive role when it comes to curricular subjects and career path choice. Students can choose the kind of non formal places they visited and they also react to TV programmes, newspapers and magazine articles about science issues, according their own interests. However, some international meetings (especially those environmentally related), and commemorative years (such as the International Year of Biodiversity, 2010), can arouse students for science issues, further broadening their prior interests.

Prior knowledge, Mass extinctions and loss of biodiversity

When we want to assess the prior scientific knowledge of students regarding a specific issue, for instance mass extinctions and loss of biodiversity, we cannot forget that we are dealing with a controversial issue. This, in turn, makes assessment even more difficult. As Claire and Holden (2007) stated, many aspects can be considered when qualifying an issue as controversial: the complexity of the subject/area, emotions strongly aroused, conflicting priorities and material interests, or conflicting values, opinions and interpretations especially between scientists or research teams. In the case of mass extinctions we can see this clearly by observing the opposition between two geological interpretations: the uniformitarism and the catastrophism. The first one lays its roots in Charles Lyell"s work that argues that geological changes occur slowly and gradually, without sudden discontinuities or catastrophes; the second one ascribes the end of a specific geological time to special and diverse events, very episodic and very limited in time. In spite of Lyell"s influence in the geological community, Ager (1993), in his book *the New Catastrophism: the Importance of the rare event in geological history,* makes a new interpretation of part of Lyell"s work, allowing those two perspectives to be conciliated. As such, as Alvarez (2000, p. 178) stated, "though no scientist doubts that most of the earth changes are gradual, geologists are now free to explore occasional catastrophic events that punctuated the history of Earth", as for instance in the case of dinosaurs" extinction. According to Benton (2008), the modern era of mass extinction studies began in 1980, with the publication of the proposal that the dinosaurs had been wiped out by the impact of a large meteorite or asteroid, on the Earth. The author also claimed that this proposal, with an immensely high heuristic value but that raised a storm of protest, re-established catastrophism at the core of geology. Although recognized as being the most well known extinction among Portuguese students (it is by far the most known of the big five extinctions), four other major extinctions were also identified: the extinction of the late Triassic; the Permian-Triassic extinction; the extinction of the late Devonian and the late Ordovician one (Benton, 2008). Most geology"s books refer to these five extinction events during the past 500 million years that stand out from the rest. However, another controversial issue related to mass extinctions has to do with the 6th great extinction that occurred in the last 50 000 years. In fact, there are many reasons that justify the interest for this great extinction: firstly, the fact of being so recent in terms of geological time; secondly, the selectivity of this extinction and finally because of the controversy related to its causes, as many researches refer to human activity as the main one. Martin (2005) indicated that this extinction occurred without any correlation to climate change or any other factor than the impact of human expansion across the planet. As our species dispersed over several continents and islands, the mega fauna was mostly destroyed. According to Courtillot (2002) the Pleistocene saw the extinction of two-thirds of all mollusks, gastropods and bivalves of Western Atlantic and Caribbean, and mammals in Africa were likewise affected. Apparently, the selectivity of the extinctions of the late Pleistocene continued during the Holocene. However, as Mackay (2009) stated, the negative impact of humans starts to reach others taxonomic groups, as a result of the emergence of agriculture and animals domestication. In fact, some researchers believe that we are currently in the early stages of a major decline in biodiversity caused by humans. To diagnose the prior knowledge in Science Students (SS) and Literature Students (LS) at the beginning of high school the authors designed the following research project. Note that in Portugal this issue is not contemplated in the science curricula of previous school years. Students only learn about the division of the earth´ history in eras, and discuss some main fossil processes. The authors also considered the controversial issues that still prevail in the scientific community regarding this issue. However, since 2010 was the year of biodiversity, a specific interest in this issue is justified, regardless the small contribution of formal education for its study.

METHODS

To evaluate prior knowledge about mass extinctions and loss of biodiversity in SS and LS, a survey questionnaire was applied to a sample of 404 students with ages ranging from 13 to 18, from the Oporto and Lisbon regions (the two biggest urban communities in Portugal). The majority of students were female (n=244) and the average of age was 15,2. Voluntary participation, rather than compulsory, was stipulated by the research team. After being given a small training, 12 high school teachers were made responsible for the questionnaire application. Students usually took 30 minutes to answer to a total of nine questions. With the exception of the seventh question, all the questions were closed ones, and students were asked to put a cross signaling in the right answers. Questions two, six, eight and nine were semi-closed, given the opportunity to the students to refer other alternatives to the given ones. The questions addressed the following issues: the causes of extinctions, the groups and species of animals already extinct, the geological period of their extinction considering a geological time scale, the groups and species endanger of extinction, the main causes of present-day extinctions, the reason why these present-day extinctions should be the addressed in informal contexts of knowledge, where students acquired prior knowledge about the thematic explored and the reasons for being in a scientific or in a literature course. After some literature revision the authors wrote the questionnaire and, for the purpose of content validation, a group of four science educators and high school teachers were asked to check the questions and to suggest necessary revisions. Following this procedure, a previous study with a small convenient sample was developed to help the validation of the questionnaire. To analyze the answers of the students according to the three research questions a descriptive statistic was made with software application PASW 19. Some content analysis had to be previously made in questions number two, six, seven, eight and nine.

RESULTS

As previously stated we purposely present the survey results question by question and discuss the evidences showed by SS and LS.

Question 1: Throughout Earth's history many living species became extinct. Do you think that extinction occurred due to: a) predominantly gradually over time; b) predominantly catastrophic and localized in time.

When asked about the causes of mass extinction, the majority of the SS (63,3%) mentioned catastrophic causes, while the majority of LS (71,3%) indicated that mass extinctions happened gradually. Catastrophic and Gradual causes were simultaneously considered by 1,9% of SS. According to these results, it seems that SS are more aware of the possible conciliation of the two perspectives.

Question 2: Which cause or causes can you identify as accountable for these extinctions: a) Scarcity of food; b) Impact of comet, asteroids / meteorites; c) Climatic changes; d) Natural selection; e) natural catastrophes, like volcanism and marine regression and transgression…; f) human activity with impact in environment; g) charges divine; h) Inversion of the magnetic field; i) Other reasons.

Regarding the main causes of mass extinction, the SS three most selected answers were: “natural catastrophes, like volcanism and marine regression and transgression…” (87,5%), “climate changes” (83,7%) and “comet, asteroid/meteoroid impact” (81,7%). The LS answers differed in only one of the three main causes indicated: “climate changes” (84,7%), “natural catastrophes, like volcanism and marine regression and transgression…” (77,6%) and “human activity” (65,8%).

Question 3: Select the species (or groups) of living beings (animals or plants) that you consider extinct:

In this question almost all students picked out the Dinosaurs. In fact, the SS three most selected answers were Dinosaurs (99%), Trilobites (96,6%) and Ammonites (93,8%) and the LS three most selected answers were Dinosaurs (93,4%), Trilobites (82,7%) and Mammoths (77%). Overall, SS selected more correct answers (67,9%) than the LS (60,5%) and less wrong answers (SS - 7,5% and LS - 7,9%). Bearing in mind that the differences are not very relevant, it seems that SS have a better knowledge about this issue.

Question 4: Attempt to locate the considered extinctions in time, filling the chart above:

In spite of having a reasonable knowledge about extinct species or groups, there were few students who actually were able to correctly locate this extinction in a geologic time scale (Table 1). However, SS had more correct answers than LS, with the exception of the Ammonites, Graptolites and Toxodon extinction location in time.

Table 1. Species or groups considered as extinct and location of the extinction in a geologic time scale.

	Science Students		**Literature Students**	
	Considered as extinct (%)	Extinction correctly located in a geologic time scale (%)	Considered as extinct (%)	Extinction correctly located in a geologic time scale (%)
Trilobites	96,6%	19,4%	82,7%	3,7%
Dinosaurs	99,0%	32%	93,4%	2,2%
Thylacine	13,5%	42,9%	17,9%	22,9%
Ground Sloth	26,9%	25%	22,4%	2,3%
Ammonites	93,8%	13,8%	73,5%	21,5%
Great Auk	36,5%	17,1%	40,8%	8,8%
Dodo	61,1%	32,3%	53,6%	16,2%
Mammoths	85,6%	14%	77%	8,6%
Graptolites	87%	6,6%	75,5%	9,5%
Toxodon	76,4%	3,8%	71,4%	5,7%
Saber toothed tiger	67,3%	24,3%	57,1%	11,6%

Question 5: From the list presented above, chose the species in endanger of extinction.

When questioned about endangered species, the three most selected answers by the SS were: “Iberian Lynx” (94,2%), “Giant Panda” (68,3%) and “Siberian tiger” (63%). On the other hand, the three most selected answers by LS were: “Iberian Lynx” (83,2%), “Polar Bear” (62,8%) and “Giant Panda” (61,2%). The SS presented a number of wrong answers higher than the LS, for instance in the case of the Emperor Penguin and the Golden Eagle (45,2% and 40,9% against 29,1% 38,8%). But the opposite happened with the Koala and the Kangaroo, with a higher number of wrong answers being given by the LS (39,3% and 22,4% against 38% and 15,9%).

Question 6: Which cause or causes can you identify as responsible for the current extinctions? a) Scarcity of food; b) Impact of comet, asteroids / meteorites; c) Climatic changes; d) Natural selection; e) natural catastrophes, like volcanism and marine regression and transgression…; f) human activity with impact in environment; g) charges divine; h) Inversion of the magnetic field; i) Other reasons.

The three most widely quoted reasons for present-day extinctions were “human activity” (SS – 96,2% and LS – 92,3%), “climate changes” (SS – 86,1% and LS – 78,6%) and “lack of food” (SS – 55,8% and LS – 44,4%).

Question 7-Many experts are concerned with the number of species that have become extinct. In your opinion, why is this so worrisome?

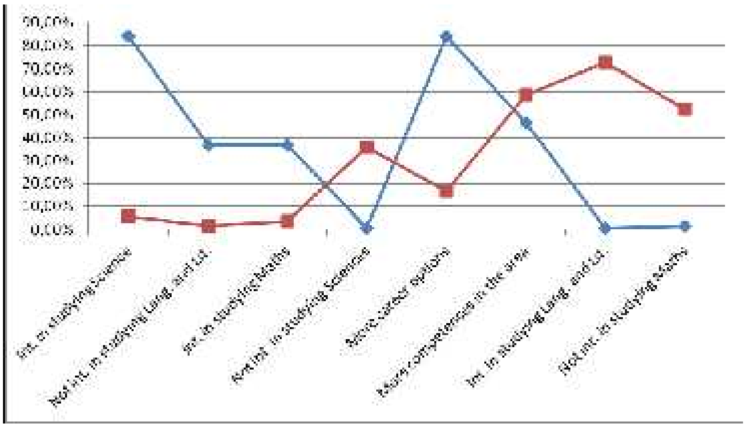
When we asked why present-day extinctions should be a matter of our concern, the main reason was the imbalance of the ecosystems (SS - 87,7% and LS - 86,8%) that can result in food chain rupture or changes in life circles caused by biodiversity reduction, which in turn can jeopardise earth‟s living beings, including humans. The second motive, referred by only 3,8% of the LS and 4,6% of the SS, points out to the lack of ethic and selfishness of Human beings. Due to anthropocentric reasons many species become extinct and many of those extinctions accelerated. Only 4,4% of the literature students and 4,1% of the science students referred to these 2 aspects simultaneously.

Question 8- As this thematic is not referred in school curriculum, how have you acquired knowledge to answer these questions: a) General Knowledge Books; b) Scientific Books; c) Television; d) Internet; e) Radio; f) Museums; g) Science Centers; h) Press; i) Scientific magazines; j) Friends; k) other reasons.

As for the main sources of information regarding this issue, the SS and the LS pointed out television (92,2% and 91%), the internet (59,3% and 63,7%) and the press (41,7% and 47,4%). Museums, Science Centers, Science Books and Radio stand out as other minor sources of information. Note that the Radio differed significantly in percentage (LS - 18,4% and SS - 5,9%).

Question 9: Select the main reasons why you have chosen to be in a science course/literature course. a) Interest in studying Science; b) Not interested in studying Languages and Literature; c) Interest in studying Mathematics; d) Not interested in studying Science; e) More career options; f) More competences in the area; g) Interest in studying languages and literature; i) Not interested in studying Mathematics; j) other reasons.

Regarding the reasons that are behind their choice, SS refer mainly to “interest in studying Science” and to the fact of Science courses offer “more options career” (84,3%). On the other hand, LS pointed mostly “interest in studying Languages and Literature” (72,8%), as well as having “more competences in the literature area” (58,6%) and “not having interest in studying mathematics” (52,3%) – Graphic 1.



Graphic 1. Reasons that lead the students to choose their course.

CONCLUSIONS AND IMPLICATIONS

Both the SS and the LS showed some knowledge regarding mass extinction, especially since it is an issue that is absent from the curricula of previous school years. However, the SS showed a better perception of the catastrophic process of extinctions and as such also revealed a higher coherence in the selection of the causes. Almost all the students of the two groups correctly identified the species and the groups that were extinct before the Cenozoic Era. The correct answers were less frequently chosen when referring to more recent extinctions, with the exception of the Mammoths. In either case, students showed major difficulties in locating extinctions correctly in a geological scale time. The SS achieved better results on this issue. Considering the identification of endangered species the results were very similar between the two groups, showing that some students hold wrong information. The informal sources indicated by the SS and the LS were very similar, with a focus in generalist media more than in science centres, scientific magazines or scientific books. This may explain why the global results between the two groups are not substantially different, and also consubstantiates the notion that formal context is still the more important context for obtaining scientific knowledge. Although the results showed some similarities in SS and LS prior knowledge in this issue, this study highlights the importance of students‟ interest in science in choosing a science course. In fact, the choice of a science course by SS is mainly due to their interest in science and their expectation in more career options. On the other hand, reasons like having more interest and competences in the literature area, as well as not being interested in studying math or science were given not to choose the scientific course. Giving the importance of this issue and according with the answers given in question 7, the authors think that it will be important to include it in a next curricular revision in such a way that it will allow the debate on the more controversial aspects, especially those ethical ones related to the 6th great extinction. This will contribute to the development of environmental responsible attitudes, increasing the science literacy and interest of young students in this issue while promoting the linkage between formal and informal education. This may also be a means of improving knowledge in other scientific subjects that are not addressed (or are superficially referred to) at school.

NEW APPROACH IN FRENCH MIDDLE SCHOOL: A POSSIBLE CONGRUENCE BETWEEN SSI AND CITIZENSHIP EDUCATION

Catherine BARRUE[1] and Virginie ALBE2[2]
[1]Laboratoire STEF, ENS Cachan, Universud Paris, France
[2] Laboratoire STEF, ENS Cachan, Universud Paris, France

Abstract: In a first time, this study aims at clarifying, who is the citizen targeted by French curriculum and what do they have in common with the one aimed by the Socioscientific issues (SSI) research movement. In a second time, questionnaires were submitted to teachers to examine how they negotiate with SSI themes and contribute to citizenship education. The analysis provided significant views of citizenship education: a citizenship education in connexion with civility and rules and a citizenship education to develop pupils' skills such as searching and evaluating information, argumentation and critical thinking in order to be able to build pupil's own argued opinion and participation to public debates. This last view is congruent with the critical emancipatory citizenship education generally promoted by SSI research.

Keywords: Socioscientific issues, citizenship education, critical citizen, middle school, teachers'practices

FRAMEWORK, BACKGROUND AND PURPOSE

Comprehensive access to scientific literacy has often been a goal for science education. Within an aim of science democratization, the education project is to equip citizens with skills enabling them to participate in society building with involvement in decision-making. Socioscientific issues (SSI) in science education research (Albe, 2008; Kolstø, 2000; Sadler, 2004, 2009) cover topics as biotechnology, environmental issues, sustainable development, energy choices...The argument that is generally promoted by the SSI research movement is a democratic participation. Although the aim of democratic participation of the population is relatively consensual, the reality seems more problematic in school context and Levinson (2010) recently raised the question of an uneasy congruence between science education and democratic participation. SSIs have been introduced in French schools through media events, official curriculum and specific teaching devices. In September 2005, the introduction of these issues was reaffirmed by new instructions in the official curriculum defining the called "convergence themes" common to several academic subjects forming the "wider scientific field" (mathematics, physics and chemistry, biology, technology, history and geography, citizenship education). The identified topics are: energy, environment and sustainable development, meteorology and climatology, statistical approach of the scientific world, health and security. They are described in the official curriculum in connexion with social issues and the educative goal is Citizenship Education (CE).

RATIONALE

This educative goal promoted by these new instructions converges with the declared SSI research aim which is generally citizenship education. This research is about the citizenship aimed to be developed: who is the citizen considered in the curriculum and targeted in the SSI research field? According to different perspectives of SSI research, emerging through literature reviews (Sadler, 2004, 2009; Albe, 2007) and some other empirical empirical papers (Colluchi-Gray, 2007 ; Gombert, 2008), this citizenship can highlight various trends. Firstly, the citizen can be involved in social and political action (Hogan, 2002 ; Patronis, Potari and Spiliotopoulou, 1999 ; Jimenez-Aleixandre et Pereiro-Munoz, 2002) through community of practices, which embody local associations for example. Following Hodson (2003, 2010) who calls for action, other researchers (Sperling and Bencze, 2010) advocated in favour of « activism ». For them science education may be considered in socio-political terms with the aim to assist childre to acquire skills for taking action to become involved as active citizen. Secondly the citizen can be considered as able to make reflective argued decisions, to evaluate the discourses of experts by understanding the Nature of Science and to participate to debates (Albe, 2008 ; Bader, 2003 ; Driver, Leach, Millar et Scott, 1996 ; Grace, 2009 ; Kolsto, 2000, 2001). Thirdly, It can be a citizen who should acquire scientific knowledge and be interested by scientific topics. Finally, in a marginal trend, a non-violent citizen resolving conflicts in a peaceful way can be aimed (Colluchi-Gray,2007 ; Gombert, 2008). Our research aims at clarifying what does the citizen aimed by the official curriculum have common features? And how teachers negotiate with SSIs via “convergence themes” to contribute to a citizenship education?

METHODS

As a first step a critical analysis of the conception of citizenship emerging from the official curriculum has been performed. The corpus was made of official texts: those relating to “social and civic skills” defined in the official curriculum as a part of *“everything that is required to master at the end of the compulsory schooling”*, those relating to “convergence themes” and those defining the academic subjects of the “wider scientific field”. In these various official documents, significant key words related to social and civic skills were identified, providing elements for understanding. This analysis allowed the identification of a citizenship profile, as targeted by the official curriculum.

As a second step, a questionnaire was built around 7 items addressing activities (1-2), practices for teaching (3-4-5-6) and teachers’ contributions, consistent with the different academic subjects through “convergence themes” (7a) and with citizenship education (7b). This seven item was attached to a short extract of official texts defining “convergence themes”. Questionnaires were submitted to middle schools teachers. With the aim to identify trends in teachers' contributions, a qualitative analysis has been conducted on the 69 answers. For the multiple choice question (1-2), a simple counting has been conduced and when the question calls for a written answer (the others), each answer was content analysed to build categories and sub-categories.

RESULTS

Who is the citizen aimed by the official curriculum?

He/she is firstly a citizen who develops attitudes and behaviors that allow him/her to be socially integrated through social codes, civility and who respect rules and laws. In addition the citizen has to feel a sense of belonging to his/her country and the European Union according to the official text defining “Social and Civic skills” and the specific contribution of historical and scientific academic subjects. This citizen has to be opened to other people and to the world,

adhering to values of tolerance and respect and taking part in community life. He/she must be aware of his/her rights and be responsible for his/her acts regarding security and health. The "convergence themes" as well as the academic subjects expand citizen's responsibility to environmental issues. A specific keyword named "choice" associated with social issues and decision-making on new technology is introduced, and the contribution of scientific and technological subjects to social, political and ethical decisions is considered. The citizen defined by official texts pertaining to "social and civic skills" has to engage in public life by addressing these social issues according to the official text of "convergence themes" that further legitimize citizen's participation in debates leading to decisions. According to the official texts defining "social and civic skills", commitment must be based on judgement and critical thinking in connexion with understanding of public argumentation, while official text defining "convergence themes" propose to built argued opinion in order to debate.
Different citizen features show a tension (fig 1) between two emergent profiles: on one side, a citizen recognised as a "virtuous" citizen who should have to acquire skills and behaviours to be socially integrated and on the other side a citizen recognised as a critical citizen being involved in choice and debate about society goals regarding issues having social, political and ethical dimensions. In the case, he (she) will have to acquire skills for "critical thinking".

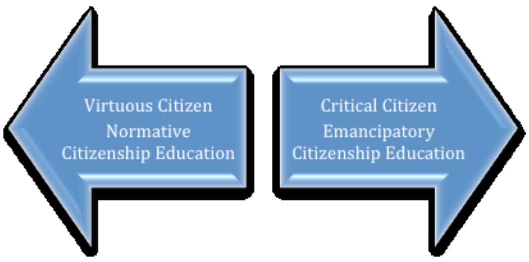

Fig 1

The curriculum analysis highlights a citizenship education oscillating between a normative education aiming at living together and a critical emancipatory education aiming at preparing pupils for decisions they will have to make in their future adult life.

How teachers negotiate with SSI via "convergence themes" and how do they contribute to citizenship education?

The distribution of the different teachers' answers to the questionnaire towards the choice of quoted convergence themes assumes a logic of academic subjects. For example, technology and physics teachers declared that they teach energy and sustainable development and biology teachers said they teach sustainable development and health. Regarding devices and practices of teaching, several teachers said they build special devices for this teaching. Some of them designed this teaching in relation with professionals. Some others designed this teaching outside academic courses as multidisciplinary devices. The answers show that teachers are aware of the necessity to involve different practices, according to the devices they design with other teachers of the same academic subject or with other persons. Still, when they were asked if they are together when teaching they answered negatively. Either they are alone, or they delegate to a professional participant working outside the school, whom they consider as most qualified to provide knowledge on selected topics. For the 7a item, three categories have emerged from our data analysis : teachers who tell they don't contribute to consistency between different subject matters; those who tell that they contribute to consistency by a collaborative work; those who refer to official curriculum. About their contribution to citizenship education (item 7b), a majority of teachers declared contributing to a citizenship education by developing pupils' behaviours, while others answered by developing new practices and a minority considered contributing by building pupils' skills. The majority of teachers expressed promoting pupils' attitudes such as civility, respect of rules, awareness of society's challenges. Several teachers underlined the necessity to change school practices and create activities that are meaningful because they contribute to a citizenship education rather than making learning a goal of its own. Their common thinking is to build a bridge between school knowledge and what they called "the real life". They considered that it is necessary to link teaching to pupils' everyday life to give meaning to knowledge, to develop debate practice about "convergence themes" which are identified by teachers as an un-established knowledge. Finally, a minority of teachers think they contribute to citizenship education because they try to develop pupils' skills such as searching and evaluating information, argumentation and "critical mind" in teachers' own words. Their aim is to form pupils to be able to build their own argued opinion. This view of citizenship education is the one we recognize as a critical emancipatory citizenship education.

DISCUSSION

Citizenship and citizenship education are complex issues that may not be considered with the same meaning in different countries. Although US, British and French citizenship, for example are not envisaged in the same way, an acknowledged link between citizenship education and SSI seems to be consensual for SSI researchers at an international scale even if different trends of citizenship views can be highlighted in SSI research literature. According to it, SSI research is rather in favour of pupils'empowerment, even if a hierarchy between SSI goals in literature research can be seen.

Data analysis of teachers' questionnaires shows congruence between teachers' views and citizen features emerging from SSI research literature. Teachers of the study seem torn between a normative and an emancipatory citizensip education. The majority of teachers who promote a normative citizenship education and a form of docility in regard to "good" behaviours can be recognized as the "virtuous citizen" having duties to others and community. The minority of teachers who promote a more emancipatory citizenship education try to contribute to a "critical citizen" building, joining the SSI-citizen, the one being able to participate to public debate and decision-making; the citizen having the will to be associated in debate and political decisions about society goals. Some questions emerge to teachers' answers about "convergence themes" teaching. They suggest that teachers are not prepared to support new practices and coach pupils in skills development and that they have to deal with a "nebulous view" of citizenship education presented by curriculum. We assume that teachers perhaps do not feel competent for this teaching or alternatively, that they show a willingness to forge links between school context and society. Official texts seem to promote intentions towards SSI but do not precise that teachers should have to develop different views emerging from society about such issues. So, teachers are not at ease to negotiate with these issues because educating citizen to participate to society choice is more complex than teaching traditional content knowledge. They cannot avoid thinking to their own role as teacher and citizen. They have to take position in favour of emancipatory citizenship education if they consider science education as a socio-political commitment and not as a pre-packaged science that pupils have to swallow.

CONCLUSION

Of great interest to us were the identification of a citizen "portrait" that would be aimed through the new French curricula and the ways teachers consider their teaching as contributing to a citizenship education. This citizen's portrait of official curriculum creates a tension

between the dominant features of the "manufacturing" of a citizen who appears consistent with some form of docility and a "critical citizen" able to build his (her) own argued, rigorous point of view and to debate in order to make choice and responsible decisions for society.
According to data analysis of teachers' questionnaires, a minority of teacher aimed to a critical citizen education through the teaching of the "convergence themes" that can be linked with the SSI citizen emerging from literature: a citizen able to make reflective argued decisions to evaluate discourses of experts in order to debate in the public field.
This case study aimed at contributing to a deeper understanding of curriculum reforms in science education that internationally promote citizenship education Our work focused on a new approach with young pupils in French Middle Schools by "convergence themes" that may contribute to an understanding of how teachers negotiate with SSI in a context of a possible congruence with a critical citizenship education. The tension that emerged from our data analysis between a manufacturing of a docile citizen and an education of a critical citizen leads us to underline that it could be desirable to promote researches about this critical citizenship education considered by a perspective of the SSI research movement and also aimed by several teachers.

THE PRE-SERVICE PHYSICS TEACHER AND THE CHALLENGE OF THE SOCIO-SCIENTIFIC ISSUES-BASED APPROACH

José Roberto da Rocha Bernardo[1]
[1]Universidade Federal Fluminense, Brasil
jrrbernardo@id.uff.br

Abstract: This article presents a study that investigated fourteen pre-service physics teachers. Starting with a partnership project between the university and five public high schools, two workgroups were formed to collectively develop didactic strategies seeking to introduce socio-scientific issues (SSI) in the classrooms of the partner high schools. The interviews with the pre-service teachers revealed that this project helped them become familiar with the theoretical framework (SSI), the school reality, and the experienced teachers' knowledge. Some difficulties in the implementation of the activities were identified, notably in relation to the lack of flexibility of school programs, the teachers' training, and the interdisciplinary nature of the SSI perspective. Regarding the applications of SSI in the classrooms, the data analyzed emphasized the role of these issues in catalyzing discussions that promote the exercise of argumentation by the students. However, they also revealed that the experienced teachers who introduced the activities seemed to have a tendency to prioritize actions in the classrooms that reinforced the development of arguments based on what is offered by various means of communication, raising the question of whether there was an actual contribution to the critical education of students, or merely an uncritical appropriation of a repertoire of arguments previously elaborated by journalists and/or specialists. These investigations are to be extended by means of a dialogue with frames of reference in the curriculum field, seeking new elements that help us understand the issues arising from this research.

Keywords: teacher training; science-technology-society; socio-scientific issues

INTRODUCTION

The way in which modern society presents itself is loaded with uncertainty and rapid change. Many changes are related to scientific and technological developments, which eventually interfere in the citizens' way of life, especially regarding ethical and moral values that cover the political, social, economic, environmental, and cultural spheres. The new millennium came bearing a series of challenges to be overcome by humankind, such as economic instabilities, climate change, AIDS, starvation, violence, terrorism, and international conflicts. This scenario places us in situations that require citizens who are well informed about global problems and prepared to play their role in society critically. This represents a great challenge to the school system and teachers, considering their function in the citizen development process.

According to Bernardo (2008), the Science-Technology-Society (STS) approach recommends the introduction of scientific contents in such a way that they could be articulated through socio-scientific issues (SSI). Science education based on the SSI approach has been considered one of the ways to introduce innovative actions into schools, based on discussions about controversial and socio-scientific topics that help students develop critical thinking skills.

However, diversity has been one of the features of this society that seems to resist any attempts to regulation. Even without significant actions promoted by youngsters against the status quo, the opposition to rules manifests itself, for instance, in the various behaviors that the different "tribes" display and that place them in radical opposition to any expectation of standardization.

In the context of education in Brazil, such conflicts are verified inside the classrooms. One of the most frequent complaints among teachers in the basic education system is related to the lack of interest by students, especially in scientific subjects—biology, physics, and chemistry. It does not mean this is their only complaint.

The first contact future teachers have with this situation involving schools and society takes place during their internship. It is usually a period marked by "reality check" (Lippe & Bastos, 2008), when the future teachers often watch practices that do not contribute much to promote the changes required by science education, and this can generate feelings of frustration and hopelessness.

According to Foerste (2005), one way of minimizing such difficulties would be to establish partnerships around collaborative projects between schools and the institutes responsible for training teachers in universities. Thus, future teachers (trainees), experienced schoolteachers, and university professors could interact to approach common interests, developing and implementing programs based on shared goals.

This study represents a subdivision of a larger project that focuses on training teachers to work according to the SSI perspective. Starting from partnership projects involving the university and five public high schools, two workgroups were formed to study the theoretical framework—STS and SSI—and to plan and implement SSI-based activities in the classrooms of the partner schools.

The initial training of the project participants and their relationship with the challenge of planning and implementing SSI activities in the classrooms were investigated. More specifically, the research questions were: *To what extent did the university-school partnership contribute to the initial training of the project participants? How did the future teachers experience the challenge that the approach via SSI represents?*

THEORETICAL FRAMEWORK

The discussion about the introduction of socio-scientific issues (SSI) in basic education has intensified in the last few decades, especially because of the situation of planetary emergency. Nevertheless, it is important to note that this matter is not new in the field of science education.

Viewed as a humanistic perspective to the science education (Aikenhead, 2008), the Science-Technology-Society (STS) approach has been recommended as an alternative to prepare citizens who are able to deal with SSI and controversial topics in a responsible way (Santos & Mortimer, 2009).

Despite the consensus points among those dedicated to interpreting how science education via STS would take place, the definition of the STS approach is still far from unanimous. What can be observed is a plurality of understandings, which can result from the complexity of the S–T–S relations and from the different notions of the theoreticians who interpret them. In this sense, many researchers took an interest in understanding the views outlined in some projects proposed until the 1990s. The studies carried out by Aikenhead (1994), for example, attempted to evaluate in quantitative and qualitative terms the presence of STS contents in relation to the presence of scientific contents usually included in traditional curricula. In both cases, a diversity of conceptions and approaches was identified, corroborating the multifaceted and eclectic nature of the STS approach.

A relevant aspect, which is almost consensual regarding STS projects, is the thematic character that guides the organization of the curriculum. Bernardo (2008) emphasizes the role of STS contextualization as a form of attributing meaning to scientific contents, through SSI that promote the articulation of several dimensions—scientific, technological, political, economic, social, environmental, ethical, moral, and cultural. This would favor an education that promotes the conscious exercise of a citizen's role when facing the challenges posed by modern life.

In relation to this subject, Santos & Mortimer (2009) suggest approaching topics that incorporate socio-scientific aspects to science classes, and claim that

> [...] from them, the teacher can develop a humanistic approach, exploring themes related to the students' experience that can arise in discussions and introducing issues related to values and attitudes. (Santos & Mortimer, 2009, p.215—our translation)

Many authors have sought to contribute to the definition of socio-scientific issues (SSI). Aikenhead (1994) emphasizes the problematic character these issues must include, functioning as "clusters" of sub-themes that are also problematic. Reis & Galvão (2009) and Levinson (2011, 2006) draw attention to the controversies that should characterize these issues, while Bernardo (2008) indicates the potential SSI ought to function as catalyzers of argumentative processes in the classroom.

This brief attempt to synthesize the topic does not consider the distinction some authors make between STS themes and SSI, as most of them do not find this discussion relevant. Nonetheless, the positions advocated by some authors, such as Zeidler et al. (2005), are worth mentioning. Attempting to separate the STS approach from the SSI-based approach, the authors use arguments based on the perception that aspects related to "moral principles and elements of virtue" do not concern the STS perspective and are the object of the SSI approach.

The introduction of SSI in schools has run into problems such as the lack of didactic materials compatible with this type of approach (Bernardo, 2008), inadequate teacher training (Sadler, 2011), and conflicts between the thematic organization of contents presented in the proposals and the programs structured over disciplines and traditional curricula. The latter happen in most schools and are the most recurring issue in our current concerns.

METHODOLOGY

The research presented here took place during 2009, 2010 and 2011. Aspects related to the implementation of didactic strategies aiming to include the SSI approach in high schools were investigated.

The activities were planned by two workgroups formed through partnerships between the university and five public schools in the city of Rio de Janeiro, Brazil. The groups were composed of one professor from the university, eight experienced teachers from the partner schools, and fourteen pre-service physics teachers working as interns under the supervision of those experienced teachers.

Beside the research goals themselves, the stages involving the planning and development of didactic materials can be identified with what Schön (1992) calls "reflective practicum," in the sense that they promoted the professional development of the experienced teachers from the partner schools as well as of the future teachers involved.

The didactic material used was produced and organized to introduce the following SSI in physics classes: "Production of Electric Energy by Means of Nuclear Plants," "Radiation in

Daily Life,” “Fuels to Move the World,” and “The Unlawful Occupation of Hills by Slums in Rio de Janeiro.”

All activities developed are strongly contextualized because they take the S–T–S relations into account, particularly the articulation among the political, economic, social, environmental, ethical, moral, and cultural dimensions promoted by each structuring theme. Each proposal involves studies on nuclear technology, radiological techniques, automotive and geotechnical technologies, and how they relate to society, which may help to catalyze the students’ reflections about the S–T–S relations. Regarding specific physical concepts, the themes explore knowledge from classical and contemporary physics in the areas of mechanics, hydrostatics, thermodynamics, electrodynamics, electromagnetism, radiation, and nuclear physics.

The activities were implemented in six classrooms, and the issues were introduced in the classes given by the experienced teachers as well as in those given by the future teachers, who always taught under the supervision of their experienced colleagues.

Apart from information about the training process involving the future teachers, this study tried to understand more subjective aspects specifically related to the implementation of these activities in the schools. These aspects included the function of the teacher, the role of the SSI approach, and the richness of the argumentative processes developed among the students in relation to the theme and the associated scientific concepts. The access to such information occurred through the perspective of the trainees and the experiences they had.

So, the research data were obtained through recorded semi-structured interviews with the future teachers and were guided by the following questions: (1) To what extent did taking part in this partnership project influence your training? (2) What aspects made it easier and/or more difficult to introduce the planned activities in the schools? The participants also commented on their impressions about introducing the SSI in the classrooms.

The interviews in Portuguese were transcribed, and the data were analyzed and categorized according to the interpretations derived from the interviews. All excerpts presented were translated by the author.

RESULTS AND DISCUSSION

The research subjects—the future teachers—will be identified, whenever necessary, as A, B … N in the presentation of the data.

The answers given to the first question were related to the categories organized as follows.

CATEGORIES	SUBJECTS													
	A	B	C	D	E	F	G	H	I	J	K	L	M	N
Becoming familiar with experienced teachers’ knowledge		x	x		x	x		x	x			x	x	
Understanding of the school functioning	x	x	x		x	x	x			x	x			x
Opportunity to experience teamwork	x			x	x		x		x		x			
Knowledge about the theoretical framework-SSI	x	x	x	x	x	x	x	x	x	x	x	x	x	x
Awareness of the S–T–S relations		x	x			x				x			x	

All the participants stressed the importance of the knowledge acquired with regard to the theoretical framework. Only five, however, demonstrated awareness of the S–T–S relations that the SSI can reveal.

Aspects related to the interdisciplinary nature of the proposals and to the teachers’ training were identified. Lack of time and the limitations imposed by school programs were mentioned. The following excerpt exemplifies some of the difficulties identified and emphasizes the crucial role of the teacher in the implementation of the planned activities, which can be related to the need for autonomy discussed by Bernardo (2008).

Participant C: "Before, I knew nothing about STS or about SSI. I think it was nice to work this way and to learn about these things […] now we have to face the addicted school structure [...] In our case, we worked in a partnership with the school [...] even though it was difficult because the principals always say that there is not enough time. I think that the stance taken by the teacher made the difference. He didn't back down. If he hadn't taken these risks, we wouldn't have been able to do this work."

Regarding the implementation of SSI in the classrooms, one of the interviews emphasized the role of these issues in catalyzing discussions that allow the exercise of argumentation by the students.

Participant B: "In my case the issue was radiation. I was afraid because it was a difficult classroom [...] I honestly never expected such a big change in their (the students) behavior. Suddenly everybody was discussing and trying hard to perform the activities I assigned them [...] I think that these issues help motivate the students to participate. And this was a difficult topic for them, because it was from the modern physics domain."

According to the participant in the following excerpt, it can be noted that the teachers seemed to have a tendency to prioritize actions involving the use of informative material rather than exploring the "scientific contents."

Participant F: "[...] there is a problem [...] the teacher couldn't make them (the students) speak scientifically. For instance, during the simulated jury, when the two groups discussed the advantages of alcohol over gasoline [...] one group mentioned that the source (sugar cane) is renewable and the other mentioned the disadvantage of having to prioritize sugar cane over other crops. The group said that sugar cane pollutes less than gasoline, but didn't justify this fact by comparing the burning processes involved. It's as if they were only repeating what was read […] without applying scientific knowledge. And the teacher also failed to encourage them to explore the whole process, as instructed by the SSI approach."

In the following excerpt, the participant demonstrates the extent to which the theme was able to drive the discussion, relying mostly on socio-environmental aspects, without failing to cover, albeit informally, elements concerning the technologies used in soil studies. Thus, the theme is identified as a discussion catalyzer, a feature that was indicated previously in the theme of radiation in daily life.

Participant M: "There was a moment in which their (the students') discussion in the classroom drew my attention. They were divided […] because the group was mixed […] there were people from all kinds of places: from slums and from residential areas. There were people in favor of occupying the hills and others against it. But, after a lot of discussion, they recognized the risks, the environmental problems, the urban impact […] and also recognized how the technology used to study the soil can help […] nevertheless, the need to have a house was the justification they used all the time."

In the following excerpt, a participant expresses empathy with the SSI-based approach, especially in relation to the theme studied. Besides, the trainee emphasizes the importance of the teacher's "courage" when confronting the *status quo*, represented by the school programs and reinforced by school culture. This may characterize one teacher's autonomous attitude. Therefore, again a participant valued the theme, involving nuclear plants, even if discussions about physics were absent.

Participant N: "What I think is that working with this theme was perfect. They (the students) loved to discuss the issue of plants in Japan because it was a very current topic […] but much depends on the courage of the teacher, because there are many difficulties with the school, the other teachers, the time frame, the program […] but they really enjoyed it. And so did I. It's a pity that they didn't explore the physics itself. They weren't even interested in explaining how a tsunami is formed. And we taught them that, but they didn't use it."

The following excerpt draws attention to the need for "complementary material" that ensures physics is learned. According to this subject's perspective and similarly to what has been presented in different contexts, the simulated debate did not lead to the acquisition of physics knowledge, because the arguments developed failed to involve the scientific knowledge related to the theme.

Participant J: "The complementary material is imperative. There must be exercise lists to reinforce knowledge about the Wheatstone Bridge, Pascal's Principle […] otherwise it seems that they (the students) don't learn any physics […] We were committed, during the creation of the activities, to making them talk about physics throughout the debate. But it's pointless […] they don't use physics to explain anything. It appears that they dodge this and explain things in the same way they did before the classes they had."

CONCLUSIONS AND IMPLICATIONS

According to the testimony of participants, working in partnership promoted an understanding of school reality and an opportunity to become familiar with experienced teachers' knowledge, the assumptions of the STS perspective and SSI-based approaches. Some difficulties regarding the implementation of the activities in the schools were identified, such as: school programs not likely to change, lack of time, teachers' training, and the need to work within an interdisciplinary perspective.

Some aspects presented here were identified in previous studies (Bernardo, 2008), especially in relation to strengthening professional identity and autonomy. These are crucial elements for teachers who intend to work using this approach in face of the challenges posed by school programs and the school culture in this case.

The comments indicate the role of SSI in catalyzing dialogue and argumentation. Nonetheless, a problem was observed by more than one of the participants regarding the incompleteness of the arguments developed by the students, which may be associated with a reductionist action by the teacher in relation to the potential of the issue to address associated scientific concepts and contents. This tendency of teachers to conduct activities in such a way that the arguments constructed by the students focus particularly on what is offered by various means of communication, was identified in previous studies (Bernardo, 2008). This could raise the question of whether the critical education of these students is actually being constructed on scientific foundations or if they are merely being offered a repertoire of arguments previously elaborated by journalists and/or specialists, conveyed mainly through the texts used in the classroom.

Of course there are still no certainties or answers regarding this issue. Perhaps we could start by pondering the difficulties involving the coexistence of ordinary language and scientific language, and how much more comfortable students can feel when basing their arguments on the former.

Another quite complex matter, which has been a challenge for us, relates to the fact that schools respond to the perspective represented by SSI with a great deal of confrontation. We have verified that other elements, for instance, pertaining to the political position of the teacher as a specialist in the subject or even the history of the development of school subjects and their constitution, have not yet been taken into account in discussions about the introduction of SSI in schools. To date, our studies have not identified, in the literature dedicated to such issues, a dialogue with the theoretical frameworks of the curriculum field or with the epistemology of the school subjects. Since we are dealing with a perspective that intends to promote a curricular intervention, it would be relevant to attempt to unveil research aspects that are more subjective and may bring about new contributions to the SSI research field.

BRINGING MEANING TO SCIENTIFIC LITERACY BY MAKING TEACHERS VALUES EXPLICIT

Rebecca Cooper[1] *and Deborah Corrigan*[1]
[1]Centre for Science, Mathematics and Technology Education, Monash University, Australia

Abstract: This paper will consider the links between secondary school science teachers conception of scientific literacy, the values related to scientific literacy they hold and how this conception and the underpinning values affect their teaching practice. Six perceived expert science teachers who teach both at senior and middle school levels and across the range of science sub-disciplines (one senior biology, one senior chemistry and one senior physics) were involved in this project, three from Victoria and three from Queensland. Victoria and Queensland are two states of Australia, each with their own science curriculum and assessment practices. Of particular note are the different assessment practices of the two states during the final year of secondary schooling and the impact this has on the teacher's prioritisation of scientific literacy and the values related to it. All of the teachers were interviewed about their understanding of scientific literacy and how this influenced their teaching practice. The six teachers were video recorded teaching a middle school science class and a senior science class. The data were analysed to identify values that underpin their conceptions of science and science education. The analysis focused on the matching of the verbalised conceptions and values of teachers with their practice of teaching science Particular attention will be paid to the way the teachers interpreted the curriculum and the role of assessment based on their values. Data of the teachers from the two different states of Australia will be compared. This paper will report on these data.

Keywords: Scientific Literacy, Teachers values of science, assessment practices, interpretation of curriculum.

INTRODUCTION

This paper considers expert science teachers articulating their practice and their notions of scientific literacy and linking these with the values they promote in their classroom both through the articulation of their ideas and their realised practice. We use the term "expert" here in recognition of the fact that these science teachers are recognised by their peers as being skilled and forms of authority in substantial aspects of the teaching and learning of science. This paper will compare the data from the teachers from two different states of Australia.

An important part of the work of science teachers is to develop some understanding of what it means to promote scientific literacy with their students and to consider how this might look as part of their teaching. One way to achieve this is for teachers to become researchers of their own practice, with the support of science education academics, paying particular attention to the values of science they are promoting to their students. Such research involves teachers giving some thought to their notions of what scientific literacy is, what a scientifically literate person can do and how they can assist students to become scientifically literate citizens. Teachers consider their notions of scientific literacy in terms of what it is they believe is important for students to be able to know and do with science. These considerations in turn lead teachers to identify the values of science that they hold and promote when they are teaching science.

Values, Attitudes and Beliefs

Values, attitudes and beliefs are central to the teaching and learning process. Halstead (1996) succinctly defines as the principles, fundamental convictions, ideas, standards or life stances which act as general guides to behaviour or as points of reference in decision making or the evaluation of beliefs or actions and which are closely connected to personal integrity and personal identity" (p. 5). However the terms values, attitudes and beliefs are often used synonymously. Hanselman (1979) has differentiated between values and attitudes. "Attitudes are enduring systems of positive and negative evaluations, emotional feelings, and pro or con action tendencies with respect to social objects. Values grow out of attitudes; they are what determine how a person is going to use his life" (p. 4).

Beliefs, while being a term often used to describe both attitudes and values, can also be differentiated from these terms, although at times this can be problematic as the range of definitions provided for belief varies significantly (see Jones and Carter, 2007, p. 1069 for a brief summary). However, Fishbein and Ajzen's (1980) differentiation between attitudes as affective constructs and beliefs as cognitive constructs is generally accepted. Seah (2002) also attempted to distinguish 'value' from 'belief' in the following ways:

- A belief is about the degree to which something is true while a value is the degree to which something is important
- A belief exists in a context while a value exists in the absence of any context.

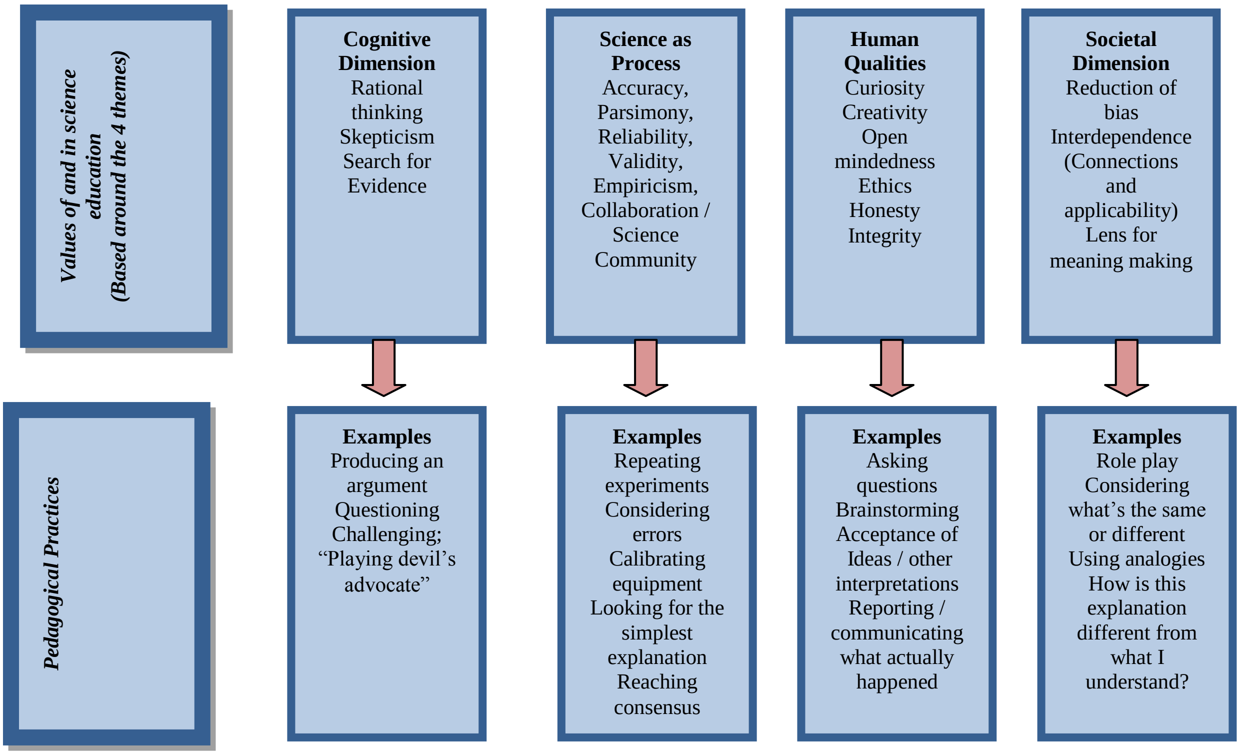
In summary, it appears that both beliefs and attitudes may be context specific, while values are not. Values and beliefs both have a cognitive dimension associated to them, while values and attitudes appear to be developed within an affective domain. What does appear apparent is the notion that values do play a large role in how our attitudes and beliefs are formed.

Values in Science Education

Values in science education include the epistemic values of science (the values of science itself), societal values and the personal values of scientists. There does not seem to be much agreement about what these particular values should be in science education across all three values types. For example, Western science has different values from other indigenous science value sets. Using the work of Corrigan & Gunstone (2007), who explored values of science under four broad themes: science as a process; human qualities; cognitive dimensions; and societal dimensions and Siddique (2008) who explored some manifestations of a number of these science values, the authors grouped the values into four groups. Figure 1, shows how these values of science may manifest in teachers' practice.

While some of the values in this framework may be open to debate and contestation (such as, is objectivity really a value or should it be something more akin to reducing bias as scientists are human and bring their own biases to their work), this framework, in linking the values with possible manifestations in the science classroom, does provide some useful insights into the often implicit teaching of science values. In this study, the manifestations were used to identify teaching practices that indicated a teacher's values; either through the teachers actions or their words. How such values relate to scientific literacy is also an important consideration.

Figure 1: Conceptual framework for the manifestation of values of science in teachers' practice



Scientific literacy – an education imperative

Another dimension to the work of science teachers is their response to the national (and international) imperative to produce scientifically literate students. Scientific literacy is associated with other forms of literacy, such as reading and mathematical literacy (OECD, 2006). However, scientific literacy also needs to account for how science knowledge is represented and communicated to students so that they can engage with science in their life.

No consensus exists for universal acceptance regarding the conceptions of scientific literacy (Osborne, 2007; Roberts, 2007), and this may be due to the dependence of scientific literacy on context. However, science education researchers agree that students must have some science content knowledge to be scientifically literate (e.g., Millar, 1996; OECD, 2006; Osborne, 2007). Roberts (2007) in his review of scientific literacy/Science literacy proposes a model to encapsulate much of the thinking in this area over the last 50 years. Roberts proposes that there is two predominate Visions of Scientific Literacy aligned at opposite ends of a continuum. Vision I derives it's meaning from within science and focuses on the products and processes of science itself. Vision II derives its meaning from the character of situations with a scientific component, or those situations that students are likely to encounter as citizens. Vision I is scientist- centred, while Vision II is student-centred.

For students, choosing a science education that is of the Vision 1 type or Vision I-II type (as there exist very few examples of Vision II type science education), means a choice for science education that has consistently led to decreased interest and lower enrolments in school science. This is largely due to Vision I with its emphasis on traditional canonical science, as opposed to Vision II, which "seeks to enhance students' capacities to function as life-long responsible, savvy participants in the everyday lives; lives increasingly influenced by science and technology" (Aikenhead, 2008, p.1). As Aikenhead points out:

> When conventional, academic, decontextualized science (a Vision 1 view of scientific literacy) changes to a contextualized science (Vision I-II view of scientific literacy in practice), the context **and content** are mostly dictated by students' everyday worlds, rather than by scientists', teachers', or curriculum developers' ideas of appropriate contexts and content for school science. Changing the meaning of "science" in the domain of school science takes us beyond policy and practice (p. 2).

Additionally, Millar (1996) suggests that this content knowledge of scientific literacy is important for both intrinsic and instrumental justifications. Intrinsic justification refers to cultural aspects, i.e., scientific knowledge can help people to satisfy their curiosity about the natural world, which is also very important in learning. Instrumental justification, on the other hand, refers to the utilitarian aspects, i.e., scientific knowledge is necessary as a foundation for making informed practical decisions about everyday matters, participating in decision-making to science-related issues; and working in science and technology related jobs (Millar, 1996, p. 9). Both of these justifications are consistent with science content applied in context, because this content may provide learners with the knowledge required in socio-scientific decision-making and may satisfy their curiosity about the natural world around them.

Aikenhead's statement and Millar's research have significant ramifications for the practice of science teachers, many of whom have grown up as learners and then teachers with a Vision I dominated science education experience. For them there needs to be a significant cultural shift in how they view science in the their classrooms that will educate their students to become more aligned with a Vision I-II or even possibly a Vision II type view of scientific literacy. Implementing such teacher change is at the heart of this project through the process of teacher research focused around professional learning.

METHOD

Our research identified, through peer recognition, six 'expert' science teachers, with whom we explored their conceptions of scientific literacy in their classroom, what values underpinned their conceptions and how this matched their teaching practice. The six teachers work in secondary schools in Victoria and Queensland, Australia and teach both senior secondary (biology, chemistry and physics) and lower secondary science classes.

Initial exploration of their conceptions and values was conducted via a semi-structured interview. This allowed the teachers to speak openly about their teaching experiences and to expand their thinking throughout the interview thus, the direction that the interviews took was determined by the researchers and the teacher as the interview progressed. This approach provided rich, detailed stories about the teachers' practice that when analysed, allowed us to identify examples of the values underpinning their teaching practice. The six teachers were filmed teaching two lessons each; one senior class and one class of year 7 – 10 science (13-16 years of age). These videos again provided rich examples of their practice in action.
The next steps in the research project included providing these teachers with an opportunity for exploring their own practices during a second semi-structured interview. Teachers were able to use both their interview and video data to comment on the manifestation of values and their notions of scientific literacy as they saw them in their practice. Finally, teachers were asked to plan a lesson that would portray one specific value to their students.

RESULTS – Values manifesting in Teaching Practice

The following is a table of excerpts from a unit of work that was written by one of the participants, Greg (pseudonym). While the participants were only asked to plan one lesson based on a value that they wished to promote, Greg found that values related well to an entire unit he was teaching on diseases and so he highlighted the values he was promoting each lesson.

Values	**Lesson description**	**Further explanation from interview**
Cognitive Dimension- *Skepticism*	Lesson 2 – 4: Movie – *what do you believe?* Watch a popular movie (I am legend / outbreak etc) and ask students to construct a list of fictional and factual references to infectious diseases throughout the movie. *Pedagogical practice*- generating what is not reasonable- fictional as opposed to factual	"But with Skepticism, we watch a movie, either *I am Legend* or *Outbreak* or *Infectious Disease*, and then they ask...yeah *Outbreak* is great. And then I actually get kids...so Skepticism, they construct a list of fictional and factual references they use in the movie... ...like that, and then they have to...whatever is fictional they write down, say why it was fictional and then turn it around to make it factual."
Cognitive Dimension – *Rational thinking*	Lesson 5: Students *Pedagogical practice*- "myth bust" the movie **using research and logic to improve the scientific credibility** for the movie producer / director. This culminates in the students writing a letter to the movie producer / director suggesting corrections for the scientific inaccuracies.	"So they came in with their...the Rationality one...so after the movie I got the kids to write a letter to the director or producer saying, "You need to change this to fix the movie."
Societal Dimension Interdependence	Lesson 9: Pedagogical practice- applying what you know and making decisions Investigation topic: global warming and the spread of disease are there links?	"Ah yeah, so Interdependence...I had just an investigation topic. Sometimes I just throw this in, with nature and science and human beings and interactions in nature. I sometimes do that if the kids are an advanced group. I try and get them to write what's the link between global warming and the spread of diseases, like sort of what the humans do and stuff like that."
Human Qualities - Creativity	Lesson 10: Pedagogical practice- Make your own disease Students design own disease in a group. They should consider: Transmission, symptoms, mortality, treatment / control, creative microscopic drawing and name of disease. Students are to present their disease to the class (gallery walk). This could be viewed as valuing science community.	"And then Creativity—I get the kids to design their own disease. So they get a piece of paper. It's like a Venn diagram but sort of a little bit different. They've got to say the transmission, symptoms, mortality, treatment, and they have to draw it microscopically. Like say if it's a bacteria, like what type of bacterial shape it is. And then you put them around the class, and they do a gallery walk so they look at all the other diseases."

Greg, along with the other two teachers who teach in Queensland, had a great deal of connectivity between the values he espoused and his pedagogical practices, regardless of the level of secondary education. Greg actually did what he said he was going to do and therefore was able to teach in ways that promoted specific values and his notions of scientific literacy with his students. The Queensland education system allows teachers a greater ability to embed their assessment practices far more fluidly within their pedagogical practices and therefore create more opportunities for informal assessment during their classes, regardless of the year level.

The Impact of Assessment

Mark (Victoria) Mark's shift in emphasis from teaching in an open and exploratory style (in years 7 -11) to teaching with a major focus on content in year 12, is emphasized in the following excerpt.

> "…you're right that content is a killer. I succumbed to it [the content] even though it's not the way I would necessarily like to teach a Year 12 year. But I've always felt, that we're doing that [working with the content] now, and I've been fortunate that I've been able to introduce another subject in Year 10 called creative science, where I do exactly what you've just explained [work in a more exploratory and open style].... and I guess for me the key here is to develop that in the Year 10 and Year 11 classes so that in Year 12 it is already part of their thinking. And then I feel that there is an opportunity to be able to do what I like to do in Year 12 given the rigors of Year 12 and the situation." (Mark, 2nd interview)

Mark's comment is indicative of those from the other two Victorian teachers, who all felt that unless they were preparing their year 12 students for the exam, then they were not doing the right thing by their students.

Larry (Queensland) Larry's consistent focus on making links between content and meaningful contexts, a feature of all the Queensland teachers comments, was irrespective of what year level being taught.

> "It's definitely about making links and I think they're….I don't know why, they don't seem to be able to see a connection between doing changing colours in a test tube and what's happening down in the creek." (Larry, 2nd interview)

CONCLUSIONS AND IMPLICATIONS

From our research it has apparent that teachers read and interpret curriculum in ways that match their value set, which in turn influences their notion of scientific literacy and the way they present science to their students. We were able to identify this through both interview data and the video footage of their teaching practice. A related factor was the impact of the assessment practices, as defined by each state of Australia, that teachers are expected to follow. Our research found that e during the final year of secondary school, a perceived higher stakes environment, teachers felt greater compulsion to teach in ways that met students' perceived needs. Their teaching practice shifts in focus to preparing students for the final assessment, rather than what the teachers feel is important for students to understand at the end of their secondary school science education.

Scientific literacy as an integral part of science education has been identified in this research as linked to teachers' values. Additionally, we have identified links between teachers' values, their interpretation of curriculum, teaching practices and assessment practices (especially at the senior level.) Teachers' values of science appear to be central here. A valuable professional learning experience is found in teachers making explicit their values of science education to generate meaning around scientific literacy and make more informed decisions about how scientific literacy can be promoted in their classroom.

STUDENTS' OPINIONS ABOUT A SSI: PERSPECTIVES REFERED IN THEIR ARGUMENTS ABOUT BEARS' REINTRODUCTION

Ana Mª Domènech[1] and Conxita Márquez[2]
[1, 2] Department of Science and Mathematics Education, University Autonoma of Barcelona, Bellaterra, Barcelona, Spain

Abstract: The use of Socio-scientific Issues in Science classes is proposed to define the curriculum's organization and design activities with the aim of encouraging students to develop scientific literacy. In this research, an activity of bears reintroduction in the Pyrenees has been designed and developed in order to analyze from which perspectives do 125 students from two secondary schools (aged 13-14) placed in Barcelona make their arguments to base their decisions about the reintroduction. Data was collected with an open-ended questionnaire included in the activity designed and the results show that students justify their opinions with different kind of arguments from different perspectives as social-oriented, ecological-oriented and moral-oriented. However, they used to use only one argument in their justifications so they show difficulties to consider the different perspectives that are related to a socio-scientific issue when they have to make a decision.

Keywords: Socio-scientific Issue, Decision making, Nature of Science, Secondary school, Bear reintroduction

INTRODUCTION

Background and rationale

Scientific literacy has become an internationally well-recognized contemporary educational goal (Nuangchalerm, 2010). Although the definition of scientific literacy is controversial, students' ability to deal with Socio-scientific Issues thoughtfully has been recognized as one of the important components of scientific literacy (Sadler, 2004). During the recent past, Socio-scientific Issues have been introduced in science classrooms and have been investigated by science education researchers (Albe, 2007).

The notion "Socio-scientific Issue" (SSI) has been proposed as a way of describing social dilemmas impinging on scientific fields (Kolsto, 2001; Sadler, 2004; Zeidler et al, 2002). In general, dealing with a SSI often involves argumentation and decision making on this issue as these are typically open-ended and ill-structured problems which citizens will find in their lives. This type of decision-making process needs to be studied in science education (Albe, 2007) and it becomes important to know how students take decisions in these contexts and how do they evaluate contradictory scientific information. Some authors considered that students are led to emphasize personal experiences or values (Sadler et al, 2004), others underlined that the overriding considerations are social or epistemological (Ryder, 2002) and some authors have questioned the importance of using scientific knowledge when SSI have to be settled.

Objective of the research

Giving the theoretical framework just presented, the specific objective this research addressed was analyze from which perspectives do students make their arguments to base their decisions about the bear reintroduction. In this study, in using the term "perspectives", we are referring to the type of information (for example, as preference for either scientific or social information) participants used in the arguments generated in a decision-making process.

METHODOLOGY

Data collection

Research population

In order to achieve the objective just presented, an activity related to a SSI was designed and carried out in two secondary schools in Catalonia (Spain) in a science class in the context of formal education. Both schools are situated in towns near Barcelona but students from school 1 come from a low social and economic bracket, with 65% of them being immigrants mainly from South America and The Maghreb while students from school 2 come from a medium to high and cultural bracket, with 10% of them being immigrants. A total of 125 students (66 male and 59 female, aged 13 to 14) took part in this study.

SSI classroom activity design

The first phase of the research consisted of designing the classroom activity and the open-ended questionnaire we would develop and use to collect research data. After knowing which students would participate, we select with their science teachers which SSI would be the most suitable, positing the premise that incorporating these issues in science classrooms has to be related to scientific knowledge studied (Barab et al, 2006). As a consequence, it has to be an issue related to what students had studied in previous lessons and to scientific contents and competences defined by Spanish curricula. Considering these requirements, ecology bloc was selected as one of the most suitable subject for carrying out our activity and, as the United Nations declared 2010 to be the International Year of Biodiversity, bears' reintroduction in the Pyrenees was considered the most adequate subject for carrying out our activity.

In 1996 bear reintroduction in French Pyrenees began with the support of Live Program of the European Union and Catalonian Government although there were different groups against this initiative. Since then, it became a local controversial. As with all SSI, politics, economics and cultural aspects play an important role in decision making about bear's reintroduction in the Pyrenees. This issue is a social dilemma impinging scientific fields because people have to decide if this initiative continues and more bears are reintroduced in this territory where bear disappeared as a result of hunting. Since this initiative was proposed, there have been different stakeholders that have opposed to and it is an issue that usually appears in the media. Although the students who participate in this study did not live in Pyrenees, researchers thought that it was important talk with them about this reintroduction because they probably will have to face with species reintroductions in the future and make decisions about them as citizens.

Once the classroom activity and the open-ended questionnaire have been designed, they were presented to an expert group composed by teachers and science education researchers who analyzed them and made suggestions which were then incorporated. In the second phase these instruments were applied.

The activity designed lasted 2h and was carried out on February 2009. It was divided in two sessions. At the first one, students read news about bears' reintroduction and the controversy related to it in order to being introduced to it. When students already knew this information, they discussed in pairs about the different viewpoints supported by all the stakeholders implied in this issue (as politicians, scientists, hunters, farmers or environment organizations for example). After discussing this information with the whole class, students read and discussed scientific information about bears' and its ecological requirements taking into account students should use these concepts in their decision making. Then, students were asked to respond individually to the following open-ended questions and wrote down their answers:

- *Do you think that bear reintroduction should be done in other place where people would not be hurt by bears? (Justify your opinion).*
- *Do you think that now we can't know what consequences will have bear reintroduction so we need do more researches in the field? (Justify your opinion).*
- *How do you explain that scientists have not achieved an agreement about the bear reintroduction? Justify your opinion and explain how do you think it could be reached*

In the second session students had to write an argumentative text presenting their personal opinion about bears' reintroduction after following a guide and discussing it in groups before explaining what they have learned in this lesson and which changes would propose in order to improve the classroom activity development.

Data analysis

According to other similar studies and to our research aims, qualitative methods combined with quantitative parameters of analyses were employed. The first phase of the analysis consisted of categories definition following an inductive-deductive method. As a first step of inductive analysis of the data (Lincoln & Guba,1985), questionnaires responses were read in order to make preliminary notes regarding patterns emerging from data. As a second step, the emergent categories were compared with the categories obtained in other studies and then they were used to classify the arguments given by the students in their responses. The second phase of the analysis was analyzing the frequency of the categories considering qualitative indicators and quantitative measures described in Wu and Tsai (2007) as will be explain in the next point. All this process was made by an independent examination of data done by investigators and the support of Atlas.Ti.

RESULTS AND DISCUSSION

In answer to the question *"Do you think that bear reintroduction should be done in other place where people would not be hurt by bears? Justify your opinions"*, students justify their opinions generating arguments from different perspectives. After categories definition following an inductive-deductive method, in this study, as is shown in table 1, learners generated their arguments from different perspectives such as "social-oriented", "ecological-oriented", and "moral-oriented" perspectives.

Category	Key words	Exemplar	% students refer to
"Social-oriented" arguments	Welfare or safety		67%
Focus on human	Human's welfare or safety, economic aspects	*"In my opinion bears should be out of the Pyrenees to prevent the bears will eat sheeps"* *"Bears should be in another place because if they are in the Pyrenees, people will be afraid of them"*	36,8%
Focus on bears	Bears' anthropomorphism, bears' welfare or safety	*"Bears should be in another place because if they continue in the Pyrenees, they will be afraid of people"* *"I think bears will be better in other place because they will be safer and live quietly"*	30,2%
"Ecological-oriented" arguments	Habitats, extinction, ecosystems, food chains,	*"I think bears should continue in the Pyrenees because it's their habitat"* *"Bears' reintroduction should continue to avoid its extinction"*	12,3%
"Moral-oriented" arguments	Right to live, behaviors or beliefs considered to be good or bad	"*I think that bears should be in other zone because if they hurt people they have to be punished"* *"Politicians should take into account that all species have rights and Earth is our planet"*	20,7%

"Table 1. Categories and frequency of perspectives from which students make their arguments to base their decisions about bears' reintroduction"

Social-oriented arguments were based on the welfare of society or human sympathy and an example is *"In my opinion bears should be out of the Pyrenees to prevent the bears will eat sheeps"*. It is important to note that, in the analysis, authors considered that it was important to point out that there were students who referred to anthropomorphisms talking about bears as if they were people and, in their arguments, refer to bears' welfare. An example of these kinds of arguments was *"Bears should be in a territory where they can't be afraid and live safety"*. On the other hand, there were students who justified their opinions with the same arguments but pointing their point of view on humans: *"I think bears should be in a territory where people can't be afraid by them"*. As a result of this fact, authors distinguished two subcategories in the "social-oriented" category depending on whether students focused on talking about humans' or bears' welfare.

In contrast, ecological-oriented arguments referred to the interactions established between species and the environment where they live as it can be seen in this example *"I think bears should continue in the Pyrenees because it's their habitat".* It has to be considered that successful biological conservation management programmes like reintroductions also depend on an understanding of the biology of the organisms concerned, and how they interact with their surrounding environment (Grace & Ratcliffe, 2002).

Finally, moral-oriented arguments were related to attitudes, facts, behaviors or thoughts that were considered good or bad, for example *"I think that bears should be in other zone because if they hurt people they have to be punished"*.

These results were consistent with Wu and Tsai (2007) analysis because in their framework they determinate that in a SSI, learners may generate their arguments from different perspectives such as social, ecological, scientific or technological. Nevertheless, there were some differences that we would explain. In our study, economic-oriented arguments were included in social-oriented perspective because authors considered that economic safety is part of society welfare's. On the other hand, science-oriented arguments were represented by ecological-oriented while technology-oriented arguments were not represented because students didn't identify a technological component in this SSI. It is important to note that, although moral-oriented arguments were not distinguished in Wu & Tsai study, moral perspective is recognized in other studies like Fensham (2002) and Albe (2007). As SSI are of a contentious nature, they may be analyzed according to different perspectives, they do not lead to simple conclusions and often they involve a moral or ethical dimension (Sadler, Chambers, & Zeidler, 2004).

Another interesting aspect is to analyze how many arguments are provided by learners. In this research, students utilized, on average, only one argument to justify their opinion (mean = 1,27) although there are different perspectives related to this SSI. These results do not concur with results obtained in Sadler, Chambers, and Zeidler (2004) and Yang and Anderson (2003) where learners were oriented to reason from multiple perspectives. Despite this difference, in this research, students who justify with more than one argument use to base them on different kind of perspectives and ecological-oriented considerations where the less proposed as occurred in the studies cited above. This trend might be due to their insufficient abilities to make the connections between what they had learned in science classrooms and the SSI they encountered in daily life (Wu & Tsai, 2007). Contrary, Kolsto (2001) argued that students' knowledge acquired in science classroom can serve as tools for their informal reasoning and decision-making on controversial issues.

CONCLUSIONS AND IMPLICATIONS

In the present research, students generate their arguments on bears' reintroduction from different perspectives as social-oriented, ecological-oriented and moral-oriented. Despite this fact, the results of this study suggest that students have difficulties to consider all these different perspectives related to a SSI when they have to make a decision, so, it is suggested that they are not able to reason from multiple perspectives. Moreover, ecological-oriented arguments were the less use although students have studied ecology before doing this activity. As a result, this study shows that students also have difficulties to use scientific knowledge when they make a SSI decision.

Taking this into account, it would be important to carry out activities to promote the analysis of the controversy from different viewpoints and to facilitate the scientific knowledge transfer to SSI decisions. To example this idea, in our classroom activity development we would design a set of new exercises in order to emphasize the science and values that each stakeholder implied in bears' reintroduction draw upon to justify their ideas while students understand they will need to know these information to be able to justify their opinions. On the other hand, the instructor could also explain the relationship between the SSI and the concepts covered in class or share their viewpoints as long as they explain how they use facts to come up with their view or resolution.

In conclusion, further research will be needed in order to improve our understanding of decision-making related to SSI. In particular, some studies can be conducted to examine deeply how students make decisions in these contexts and describing which teaching strategies could be used to enhance students' learnings transfer and engaging them in scientific practices in order to help them understand the nature of scientific knowledge.

MIMICKING AUTHENTIC SOCIETAL PRACTICES FOR LEARNING ABOUT THE USE OF SCIENCE-RELATED INFORMATION

Ingo Eilks[1]*, Ralf Marks*[1] *and Mareike Burmeister*[1]
[1]University of Bremen, Germany

Abstract: Modern standards for science education ask for promoting scientific literacy for all students. One of the central objectives is that all students should develop skills to be able to actively participate in societal debate on applications from science and technology. One of the central prerequisites for participating in societal debates is the competence of doing evaluations. But, evaluation competence covers several different dimensions: evaluations in science, evaluation about science, or reflecting evaluations done by others. This essay discusses using the socio-critical and problem-oriented approach to science teaching as a basis for learning about evaluation processes with regard to societal questions of science and technology. The idea of filtered information will be introduced for better understanding the process of evaluations done by different groups of persons in society. Learning about filtered information is operated by mimicking authentic societal practices in which science-related information is filtered and used. Examples and experiences from lower secondary science classrooms are reported.

Keywords: science education, curriculum development, scientific literacy, socio-scientific issues, filtered information

LEARNING ABOUT EVALUATIONS IN SOCIETAL-ORIENTED SCIENCE EDUCATION

A central objective of developed scientific literacy (Bybee, 1997) is to become able to understand and to participate in societal debate concerning questions of science and technology (Roth & Lee, 2004). Although the goal is not new and respective standards are now available for quite a long time (e.g. AAAS, 1993; NRC, 1996) the practice of science teaching in many countries is still neglecting the societal dimension of science education and the promotion of respective skills for active participation in society (Hofstein, Eilks & Bybee., 2011).

In the core of the skills to take up own interests in society and to participate in societal debate is the competence of doing evaluations (KMK, 2004). In contrast to other areas of science education, the competency of doing evaluations has typically not been taken into account very seriously in many traditional science curricula (Marks & Eilks, 2009). This observation becomes even truer when we understand the area of evaluation not just as evaluating *in* science (in other words, evaluating the processes of knowledge discovery, measurements and learning results), but rather as communication and evaluation *about* science (an evaluation of the role of science in technical, economical or societal developments).

Need for change towards more societal-oriented science education and a more through focus on learning to do evaluations gains growing support from different theoretical resources. In the German-speaking realm, this view coincides with the concept of *Allgemeinbildung* (e.g. Elmose & Roth, 2005), defined as the educational upbringing of pupils to be responsible citizens characterized by the abilities of self-determination, participation, and solidarity in a democratic society (Klafki, 2000). This view is also in accord with an understanding of scientific literacy as being multidimensional (Bybee, 1997) or rethinking traditional science education from purely "*Science through Education*" approach, in order to adapt science lesdsons into a program of "*Education through Science*" (Holbrook & Rannikmae, 2007).

As said above, examples and justifications for a more thorough orientation of science education towards its societal embeddedness are not new (Hofstein et al., 2011). Today many of these approaches are subsumed under the headline of socio-scientific issues based science education (Sadler, 2004). The most prominent example of this orientation of science education in German-speaking countries is the socio-critical and problem-oriented approach to chemistry and science teaching by Marks and Eilks (2009). Such lessons demand that authentic societal controversies be investigated in science classes. These controversies provide not just a chance to learn the subject matter-based aspects of the topics in a motivating situation, but also to uncover opportunities for pupils to directly interact and deal with such conflicts, including how to personally take part in them.

THE IDEA OF FILTERED INFORMATION

Within every science syllabus the learning of science subject matter knowledge is described. Also we find in almost all curricula objectives focusing the nature or science, e.g. to learning about processes of scientific knowledge generation or understanding the nature of scientific models. The students should learn to evaluate and reflect the potential of science and scientific information to solve problems and how reliable and secure scientific knowledge is. The students should learn to be able to estimate and evaluate scientific discoveries and information, especially with respect to the principally temporary character of such knowledge and theories.

Without wishing to devalue this viewpoint or drive it out of the science classroom, we do believe, however, that we should somewhat relativize - or at the least expand - this way of thinking. We need to be conscious of the fact that only the tiniest fraction of our pupils in mandatory school science classes will ever come into contact with authentic science and/or emerge with the capability of evaluating such things. We should be aware that most scientific information the vast majority of our students will come into contact with is not from resources from within the community of scientists. Such 'scientific' knowledge can be found in scientific journals, conferences, or academic books of science. Access to such knowledge, despite populist representations of science, is limited to scientists. Only scientists have access to the original scientific literature and only sufficiently educated scientists are able to understand the texts and presentations in question.

As soon as we start to examine populist literature forms or school textbooks and teaching aids, we are no longer dealing with original scientific information. Contact to authentic scientific information is not even extant in everyday situations and societal decision-making bodies, which occupy themselves with subject matter-based inquiries into scientific and technical issues. The information presented has not even been drawn from the original sources of information. Sometimes it is not even prepared by scientists with qualifications in the area in question. Nevertheless, everyone – also the non-scientists - will come into contact with scientific information. We can be certain that all of our pupils will be confronted with such scientific information presented in not-authentic scientific form in their future lives, whether the source is TV, newspapers, brochures, or advertisings. Access to scientific information via this way is prepared by special interest groups, politicians, journalists or advertisers.

The way of information from science towards us is long. Every time the original information is processed by individual groups from the above mentioned professions, filtering takes place. Each step is carried out by a person, be it a scientific journalist, news agent, regular journalist, author, editor, etc. The final product is hugely influenced by the individual foreknowledge, interests, motivation and subject matter and linguistic competencies of the writer, and also each person being involved along the filtering process. This is the same as in the children's game "silent mail", where a message is whispered from person to person down a long line, then checked for accuracy at the end: a process which hardly ever succeeds. The further we move towards everyday life, in this case towards the press media confronting us in our every lives (newspapers, magazines, radio and television), the more the information most probably is filtered and altered. The further one travels from the domain of science, the greater the chance that the filtering persons do not possess the subject matter knowledge necessary for the task at hand. E.g., we can be fairly certain that the average editor in a local newspaper responsible for creating news stories did not pursue science studies intensely and actively after his or her formal science education in school was over.

Thus, contact with scientific information in everyday settings may not just be a simple evaluation of the pertinent knowledge. Frequently, it is just as – if not more - important to understand which pathway the transmission of information followed and exactly which interests have played a role in the transportation of this knowledge. Widely different people have played a part in the process. It goes without saying that such groups as lobbyists, special interest groups, advertisers and politicians have and are following their own agendas. Yet journalists also possess interests, even if they are as relatively clear as the wish to bring an attractive journalistic product to market, one which is offered with an eye towards potential customers by specifically selecting and preparing information for the target group in an interesting fashion. It has already been mentioned that the subject matter qualifications of the author are most often not clearly recognizable. But the filtering process is by no means determined solely by the knowledge-based professional competence of the author. Of equal importance are such factors as personal interests and the competency to represent and pass on information in a solid, understandable and objective manner (or at the least to intentionally and self-consciously craft such representations in a fashion which mirrors reality as closely as possible). In this regard, a double-filter mechanism can be recognized (Figure 1).

Figure 1: The doubled filtering process of scientific information

These filtering processes can quite possibly exert more influence over the individual than the information itself. Understanding this filtration is directly related to understanding how to (re)act towards such information. This is true, for example, in the case of determining the credibility of an information source. Learners must develop mechanisms for evaluating such things. This includes working out various strategies like self-consciously contrasting different pieces of information quite possibly stemming from sources with diametrically opposed viewpoints, in order to finally classify the information presented by all of the sources. But the question of exactly how such filtering takes place and how we are to deal with such an event is of critical importance for even approaching such information. Yet most science instruction barely even broaches this issue let alone makes it into an element of overall teaching goals or methods.

MIMICKING AUTHENTIC SOCIETAL PRACTICES OF INFORMATION FILTERING IN SCIENCE EDUCATION

The socio-critical and problem-oriented approach to chemistry and science lessons (Marks & Eilks 2009) aims especially at the development of interdisciplinary communication and evaluation competencies. It does this in addition to attempting to increase levels of student motivation and the perception of relevance by constructing meaningful connections between basic subject knowledge and learning. These units start by selecting authentic societal controversies. They are structured using authentic media and consciously choose to employ two methods: attesting one's opinion and debate. In order to learn about societal discourses, methodology is selected, which contrasts the various opinions found in the public forum (Figure 2).

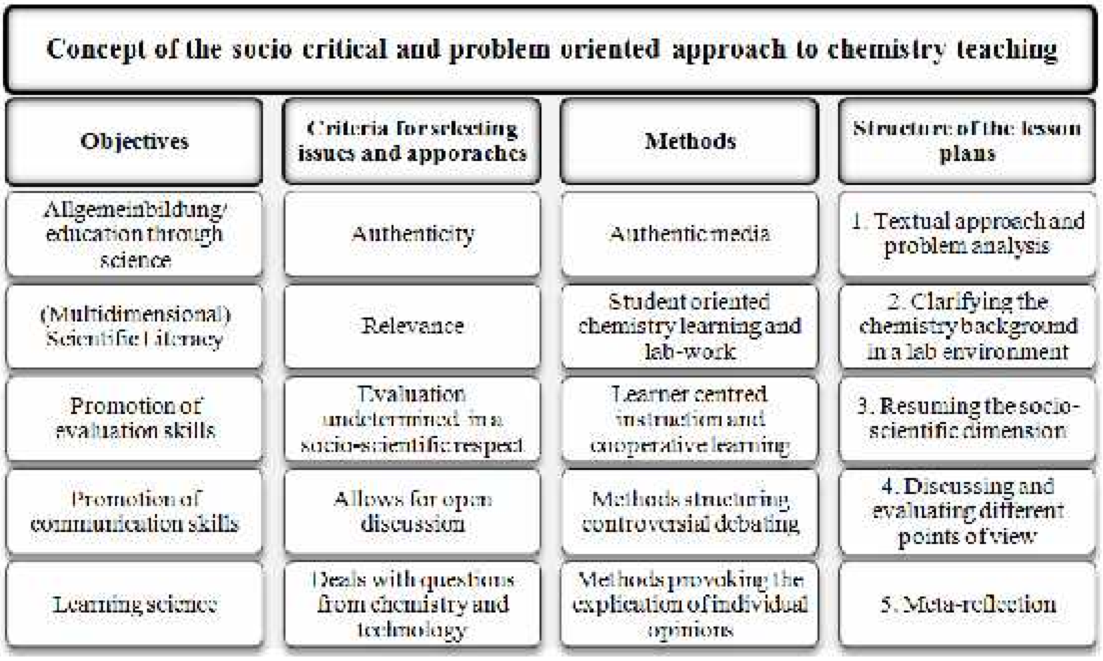

Figure 2. Model of the socially-critical, problem-oriented approach to chemistry teaching (Marks & Eilks, 2009)

Contrasting of various opinions (Figure 2, column 4) is methodologically achieved by mimicking authentic societal practices which either transport this type of information within society, carry out debates, or make decisions about such controversies. A commonly known possibility is offered by role-playing exercises (e.g. Marks, Bertram & Eilks, 2008) in which various opinions are represented and societal discourse is imitated. However, the potential yield of role-playing and planning games has often been criticized. The necessary preparation is very time-intensive and pupils' competency in debate and argumentation techniques is often not up to the task. Especially younger, unpracticed students cannot present their arguments in an eloquent manner and carry out their reasoning in a somewhat helter-skelter, non-integrated fashion. This is especially the case when a topic has only an indirect linkage to their everyday lives. When this occurs, the role which the learners are required to act out remains unfamiliar.

Students have difficulties with the complexity of the role, because they do not possess the necessary, accompanying background experience. Because of this, the role-players cannot react flexibly enough and tend to stick to a "script" with regard to their assigned position. But role-playing exercises are generally quite successful whenever the learners bring a large amount of personal experience with them. This was our experience for a teaching unit based on dieting (Marks, Bertram & Eilks, 2008), since our pupils already understood the TV talk show format and had already done a lot of personal thinking about the topic beforehand. Abstract topics like climate change, however, tend to make this process noticeably more difficult (Feierabend & Eilks, 2010). Pupils do not possess extensive personal links to the topic, even if it is frequently discussed in the media.

Due to this factor, we classify methods with clearer structures as those having higher potential. This is true whenever we actively begin categorizing the broad spectrum of available teaching examples (see Table 1). We have increasingly developed such methods within the socio-critical and problem-oriented approach to science lessons. Development of all the methods was inspired through processes of mimicking the work of such people doing the filtering and evaluation processes, like journalists, consumer product testers or advertising specialists. Table 1 gives an overview of previously documented teaching units and potential scenarios.

Place/filter medium	Imitation of societal practice	Example
Open discussions	Role-playing of a TV talk show or podium discussion	Debate about diets (Marks, Bertram & Eilks, 2008)
Announcements from interest groups	Analysis of brochures and podium discussions	Biodiesel (Eilks, 2002)
Political hearings and committees	Committee of experts planning game	Climate change (Feierabend & Eilks, 2010)
Press and broadcasting news	Journalist method (Marks, Otten & Eilks, 2010)	Shower gels (Marks & Eilks, 2010)
Product testing	Product test method (Burmeister & Eilks, 2011a)	Plastics (Burmeister & Eilks, 2011)
Advertising	Creating advertisements	Sweetening agents (Lippel, et al., 2012)

Table 1: Teaching examples for the imitation of societal practices

EXPERIENCES AND IMPLICATIONS

Science teaching has constantly been a target of criticism. It is, i.e. in the fields of chemistry and physics, perceived as being uninteresting and irrelevant by pupils. The usefulness and value of the subject matter taught and competencies learned in science, i.e. chemistry and physics, class remain frequently unrecognized. The here presented approach, documented up to today for more than 15 different units and developed and tested by Participatory Action Research in science education (Eilks & Ralle, 2002) documents that a thorough orientation on controversial and authentic socio-scientific issues can provide a fruitful alternative.

Numerous case studies testing the socio-critical and problem-oriented to chemistry and science teaching (e.g. Eilks, 2002; Marks et al., 2008; Marks & Eilks, 2010; Feierabend & Eilks, 2010; Burmeister & Eilks, 2011), provide a whole set of evidence that a stronger orientation towards society and a more attractive structuring of material both represent enrichments to teaching, which may possibly help to reduce the deficits discussed above. Learning about the interconnectedness of science, everyday life, and society has continually shown itself to be a motivating factor. This always was one of the positive factors in the feedback and evaluation of respective lesson plans. Anyhow, aside the motivating factor positive feedback especially focused the alternative methods of teaching, i.e. creative ways of contrasting different points of view in the mimicked authentic practices. Here methods providing clear structure (e.g. the journalist method by Marks, Otten & Eilks (2010), the consumer test method by Burmeister & Eilks (2011), or developing advertisings by Lippel, Stuckey & Eilks (2012), are considered to be more fruitful than the often more demanding methods of role plays and business games. For motivating and explaining the use of mimicking authentic social practices the idea of filtered information has proven itself to be a valuable construct. This is true for both lesson planning and reflection, but also for discussing with pupils how science is dealt with by society.

After the intensive trials of the examples presented here in different groups of Particpatory Action Research, we are convinced that science lessons following this path represent an important contribution to broad-based, societally relevant learner competency in communication and evaluation in the sense of general educational goals. Our experience also reveals, however, that not only pupils, but also their teachers, can learn and benefit greatly from the intentional networking of science, technology and society. Therefore, respective lesson plans and methods should be more thoroughly incorporated into the practice of science teaching.

SCIENCE EDUCATION FOR CIVIL SOCIETY: BRIDGING THE GAP WITH MICHEL FOUCAULT AND PIERRE BOURDIEU

Michael Geiger [1]
[1]Universität Oldenburg, Didaktik und Geschichte der Physik, D-26111 Oldenburg, Germany

Abstract: Taking as a starting point – or "as a startling point" as one might say – the phenomena that occur when moving within the two fields of science education and civil society, the article gives a short overview of the fields of science education and of civil society and how they look at each others objects of description respectively. A veritable white spot on the map between theories of civil society and of science education is detected and found to be both fascinating and disturbing. To bridge the split the philosophy of Michel Foucault and the sociology of Pierre Bourdieu are considered. An exposition of elements of the works of M. Foucault and P. Bourdieu supports the argument that both are helpful in understanding how science education for civil society may function.

Keywords: civil society, epistemology, philosophy, bourdieu, praxeology

INTRODUCTION

Providing a short overview of the fields of science education and of civil society and how they look at each others objects of description respectively, this article describes a veritable white spot on the map between theories of civil society and of science education. The author considers the philosophy of Michel Foucault and the sociology of Pierre Bourdieu to bridge the split. An exposition of elements of the works of M. Foucault and P. Bourdieu will support the author's argument that both are helpful in understanding how "science education for civil society" may function.

A STARTING POINT

Data collected as a participant observer in the two fields of science education and civil society in Germany over several years (as a science teacher, as a committed citizen, but also as a science student and later as a doctoral candidate) led the author of this article to a hypothesis inter alia that in most Germans' everyday thinking, the undertaking of science education in school is not or only very weakly linked to participation in a civil society (Geiger, 2009). A similar split can be found, when looking into the theories that describe and (re-)construct civil society and science education:

THE TWO FIELDS

To gain an overview of the theoretical construction work that is done on the field of German science education, one can take a look, for example, at the list of contributions to the 2010 annual conference of the German Association for the Didactics of Physics and Chemistry (GDCP 2010) or into the German journal for the Didactics of Science (ZfDN 2010). Even though the 2010 conference was titled "Naturwissenschaftliche Bildung als Beitrag zur Gestaltung partizipativer Demokratie" (translated: "Science education as a contribution towards participative democracy"), the topic of its title can be found almost nowhere in the contributions. Apart from the keynotes, only 7 out of 147 single oral presentations explicitly address participation, democracy or civil society. A first look into ZfDN gives a similar picture: There is a small fraction of authors making notions towards a democratic society. But the links are drawn more or less in “hand waving” manner, mostly with the purpose of providing moral background support to their special approach within the field of science education. Detailed models or empirical evidence of concrete links between science education and the functioning of civil society are never mentioned as an integral part of the reasoning on the science education side.

The split seems to be even wider, if one looks into the common theories of civil society. Heins (2002) and Schmidt (2007) give an overview of authors like Alexis de Tocqueville, Max Weber, Antonio Gramsci or Hannah Arendt. Even though these authors have been constructing their theories while industrialisation (and thus the growing importance of scientific knowledge within society) was already fully on its way, none of their theories seem to contain any important notion towards science education. It is the same with more recent authors like Barber (2003) or Walzer (1992). Although Barber talks of “politics as epistemology” and later gives a detailed and concrete list of institutions to be introduced into our democratic societies, there is not a single substantial word on science education.

While the view on the bodies of the different theories can and has still to be improved, the division between the theories in the two fields is already clearly visible. It seems that we are still in the era of “The Two Cultures” of 1959 (Snow, 1993).

SORROW AND FASCINATION

The split between science education and civil society theories is both fascinating and disturbing at the same time. One only has to take into account two commonplaces: 1. To a high degree, the very fabric of modern societies is made of and sustained by technologies and their underlying scientific knowledge. 2. The stability and healthy transformations of modern liberal democracies are regarded as hinging on active civic participation of their citizens (e.g. Barber, 2003). Both put together, the theoretical unconsciousness regarding the interdependencies between science education and civil society appears as a major impediment, probably imposing itself onto the necessary and certainly ongoing transformations of existing democracies. This unconsciousness furthermore indicates that there are sub-surface mechanisms, probably of various kinds, that foster the existence of that split.

TWO SCHOLARS IN BETWEEN

Once again when looking for theoretical frameworks to bridge the gap, my aforementioned empirical findings of the participating observations in the two fields of science education and civil society serve as a starting point. The works of Michel Foucault (1926–1984) and Pierre Bourdieu (1930–2002) seem to prove particularly helpful in trying to find theoretical explanations and descriptions for those findings. I will present some exemplary elements of the works of Foucault and Bourdieu, to demonstrate that both of them are able to shed light onto some important aspects of what lies in the dark between the two fields.

A striking similarity between Foucault and Bourdieu is, that their works are explicitly aimed at barriers of perception easily escaping our consciousness. Both follow different pathways to accomplish the unveiling and possible dissolution of such barriers. Foucault, for example, somehow travels in time – or rather history – via documents of the past, whereas Bourdieu travels in space – examining cultures to be found with the groups of different places. By displacing themselves, they both gain distance to our present and here. Looking back from what they find at their distant places, our European society at the end of the 20th century suddenly starts looking alien, coincidental – sometimes even comical ! – thus revealing some of its implicities, that would not have otherwise been seen at all, or would have passed as normal, necessary, natural.

Michel Foucault

Michel Foucault was interested throughout all of his works in the different relationships between knowledge, power and humans. He took special interest in how humans become subject to those relations by techniques, technologies and practices.

His works are situated exactly along the axes that are being of interest to the research of links in between the two fields. An example would be one of his later lectures (Foucault, 2009): He analyses the relationships between human subjects and truth and the practices humans use or have to use to gain access to truth. In this lecture, he describes something he calls the “cartesian moment”: From that certain moment on – it is a long and discontinuous road leading to that moment – one can say that legitimate, justified truth is won by and only by perception of objects and knowledge on objects. From this moment on, truth has become objective truth. As such it is the basis of modern science. And it is separated from the subject perceiving it: We discuss and quarrel about methods and we require that a researcher is honest, is rational and has undergone some training. But once we agree on the methods and those prerequisites are met, the knowledge acquired is objective truth, independent of the person researching. By examining some mainstream philosophies of the 1st and 2nd century, Foucault shows that there have been other reasonable concepts of knowledge and truth: In stoic and epicurean thinking, knowledge was to link the individual subject to the world and the worldly objects – it was subjective knowledge. A teacher was seen as speaking the truth only, if his speech was able to lead his listeners towards autonomy from the speaker.

One only has to take a look at today’s practical circumstances between experts and non-experts, teachers and students to realize the differences ... A hypothesis, among others, that could be drawn from Foucault's historical perspective on truth above would be, that the truth dominating science education is an objective type, whereas the kind of truth that is needed in and would be helpful to the processes of civil society would be both objective and subjective. It would arise, for example, from working on questions like: “What does that objective truth mean to me personally (as citizen among others)?” Problems arise, if one wants to integrate that work on subjective truth into science education: The institutional practices of grading students' performances are constructed as objectifying acts of the teachers on the students and their works.

Pierre Bourdieu

Pierre Bourdieu has conducted vast and huge sociological explorations (some call his style of work an “academic mega-enterprise”) into various fields of society, including the academic field (Bourdieu, 2006) and the educational system (Bourdieu & Passeron, 1971). Throughout the various research campaigns and heavily relying on empirical data, Bourdieu constructed a complex, dynamic, accurate, comprehensive and up to now almost unchallenged theory of modern society.

An exemplary element of Bourdieu's theoretical framework that stems from his cross cultural observations is his concept of “dispositions” (an easily accessible description can be found in Bourdieu, 2005): This concept indicates that it is impossible to change an unequal society via simple acts of cartesian cognition (that is, by objective knowledge). Bourdieu is able to show that the individual and collective abilities to participate in society are written into peoples' bodies and minds and that those abilities correlate with their social positions and milieus. The social conditions of society are so deeply written into bodies and minds, that their effects on behaviour and perception of reality are not easily accessible by conscious efforts.

CONCLUSIONS

Looking at the state of my work, I can say that it is still far too early to draw anything like a blueprint of what science education for civil society could or should look like. Yet both Foucault and Bourdieu help identify possible elements of reflection and consideration: The small fraction of Foucault's work given above suggests that it would be worth putting an analytical focus on the conscious and unconscious gestalts of truth that play a role in science classes and in civil society. Pierre Bourdieu's concept of dispositions shows us that individuals are unable to really participate in political processes on the basis of their (cognitive) scientific knowledge alone: If science education is meant to emancipate people, it cannot ignore the effects of bodily incorporations and social environments of students and teachers. In one way or the other, it has to address those fields of learning, too.

Many concepts of science education that do this exist already, both in theory and practice. Working towards a science education for civil society would therefore certainly not mean re-inventing the wheel. But it would mean drawing lines between those concepts and civil society on a theoretically and empirically solid basis, thus introducing some new aspects and new input into both. On the side of science education, I think this bears the clear opportunity to further develop and extend (or in some cases to revive and rejuvenate) progressive approaches like “la main à la pate” (a collaborative hands-on approach), teaching history of science, STS or project-oriented teaching.

INFLUENCE OF EXTERNAL ASPECTS ON STUDENTS' EVALUATION AND JUDGEMENT COMPETENCE IN CHEMISTRY

Julia Hostenbach[1] and Maik Walpuski[1]
[1]University of Duisburg-Essen, Germany

Abstract: This study is based on the National Educational Standards (NES) in chemistry for the final exams at middle schools (KMK, 2005a, b, c) in Germany. The Institute for Educational Progress (Institut zur Qualitätsentwicklung im Bildungswesen - IQB) evaluates and develops the NES in cooperation with institutes for science education at different universities in the project ESNaS (Evaluation of the National Educational Standards for Natural Sciences at the Lower Secondary Level). The NES covers 4 areas of competence which are: a. content knowledge b. acquirement of knowledge (scientific inquiry) c. evaluation and judgement and d. communication. The project presented in this paper is limited to the *evaluation and judgement competence*, only. The presented study's aim is to clarify how students' evaluation and judgement competence is influenced by external aspects. Therefore items are developed and used for the assessment of 780 students in Germany.

Keywords: assessment, evaluation and judgement, Chemistry, standards, paper-pencil-test

FRAMEWORK

Amongst others, the National Educational Standards (NES), which are established by the Standing Conference of the Ministers of Education and Cultural Affairs, define competences for the scientific subjects (biology, chemistry and physics) and have been implemented in Germany after the school year 2005/2006 because of unsatisfying results in international studies like TIMSS and PISA. Students should have acquired these competences when they graduate from middle schools after grade 9 or 10 (depending on the school type). The standards are described for different areas of competence (*content knowledge*, *acquirement of knowledge, communication* and *evaluation and judgement)* (KMK, 2005) and are evaluated and enhanced by the Institute for Educational Progress (IQB) in cooperation with institutes for science education at different universities in the project ESNaS.

The NES define the *evaluation and judgement competence* in chemistry as the ability to detect and evaluate chemical topics in different contexts (KMK, 2005). In recent research projects in biology the *evaluation and judgement competence* is defined as the ability to decide justifiedly and systematically in complex problemsituations with different options of behaviour (Bögeholz et al., 2004). According to Poschmann, Riebenstahl, & Schmidt-Kallert (1998), an evaluation process consists of a minimum of three elements (object, subject, connection between object and subject). During this process criteria have to be identified, evaluation strategies have to be used and finally a decision has to be made (Jungermann, Pfister, & Fischer, 2005). Test items in the context of *evaluation and judgement competence* normally do not have a clear or single solution and, as socio scientific issues (SSI) in general, offer controversial opportunities (Sadler, Donnelly, 2006). These issues are mostly social, complex and open-ended problems related to science (Sadler, Barab, & Scott, 2007). They can be negotiated from multiple perspectives (Sadler, 2004). Topics represented in these issues are, for example, global climate change, energy choice or genetically modified food (Albe, 2008).

There are competence models for the evaluation and judgement competence in biology only which are specified on some aspects of the evaluation and judgement competence (Eggert & Bögeholz, 2006; Mittelsten Scheid & Hößle, 2008) but they cannot be directly adapted for chemistry.

It can be assumed that there are additional external aspects which influence the *evaluation and judgement competence*. These external aspects are not part of the evaluation and judgement competence itself but may be important control variables when measuring the *evaluation and judgement* competence. Recent research projects showed that high content knowledge effects the quality of argumentation (von Aufschnaiter, Erduran, Osborne, & Simon, 2008) and showed a relation between content knowledge and the negotiation of SSI (Uskola, Maguregi, & Jiménez-Aleixandre, 2010; Sadler & Fowler, 2006). In addition to that, it can be assumed that social desirable responding could have an influence on students' answers in surveys (Sedlmeier & Renkewitz, 2008). To assess the *evaluation and judgement competence* tasks are used which contain environmentally conscious behaviour. Under expectation of an environmentally conscious behaviour, corresponding attitudes are assumed (Kaiser, Wölfing, & Fuhrer, 1999). Critical thinking is one requirement for the *evaluation and judgement competence* and contains the evaluation of data quality (Astleitner, Brünken, & Zander, 2002) and students need to know what evaluation strategies are and they have to apply evaluation strategies to evaluate precisely.

The possible external influential aspects can be divided into the three following categories (figure 1):

1. Subject-related aspects, which include the content knowledge and the application of content knowledge, related to the topics of the items.

2. Interdisciplinary aspects, which include knowledge and application of evaluation strategies and estimation of data quality.

3. Personal aspects, which include individual attitudes, social desirability and cognitive abilities.

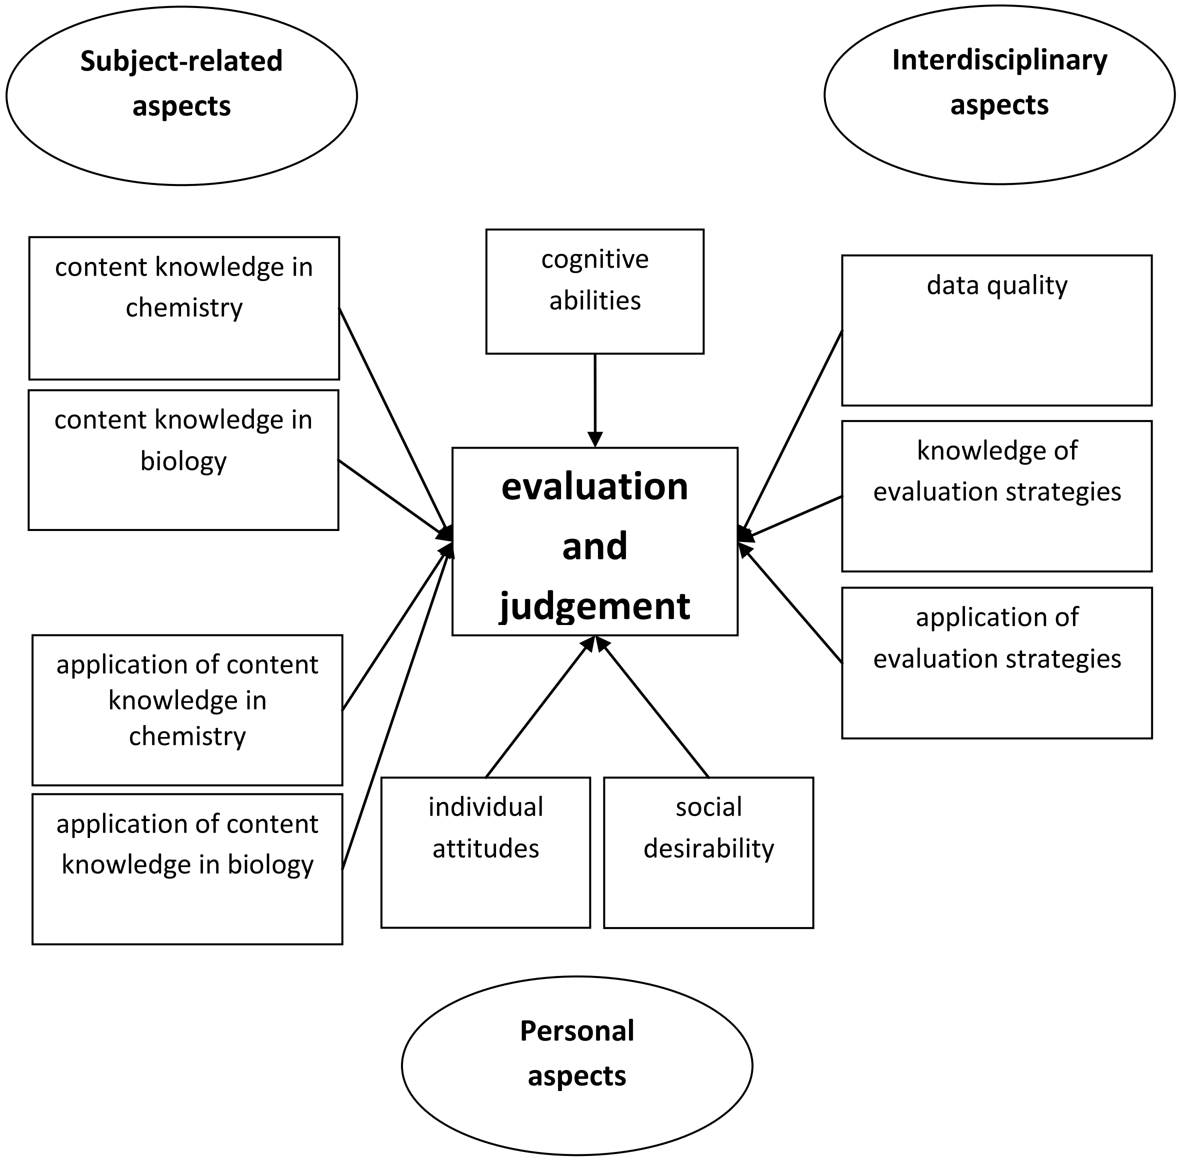

figure 1: assumed external infuential aspects

Methods

For data collection a quantitative empirical design was used. To assess the *evaluation and judgement competence* in chemistry, students had to work on paper-pencil-tests constructed in a balanced incomplete block design. In test items students were asked to identify criteria to make a decision in controversial situations, to use evaluation strategies and to reflect decisions. Additionally, the following tests concerning the assumed influential aspects were used.

- Test on content knowledge and application of content knowledge. This test was constructed in a balanced incomplete block design and the students receive the items which match the items they had in the test on the *evaluation and judgement competence.*

- To test whether the students evaluate because of social desirability, the German version of the balanced inventory of desirable responding (BIDR) was used (Paulhus, 1998; Musch, Brockhaus, & Bröder, 2002). This test consists of two scales, which have 10 items each. Social desirability is divided into two distinguishable components. While one component is self-deceptive enhancement, the other component is impression-management. Each of these components can be measured with the BIDR because of a two factorial loading structure and good convergent and discriminant validity (Musch et al., 2002).
- The cognitive ability test (Heller & Perleth, 2000) was used to control the influence of intelligence.
- A test on knowledge and application of evaluation strategies in everyday life context
- A test measuring the students' estimation of data quality
- A test concerning individual attitudes concerning environmental aspects (Frey et al., 2009)

The time needed by students to fill out the tests and questionnaires was 180 minutes and data was collected in two days. To recapitulate, there was a test concerning the chemistry specific *evaluation and judgement competence* and tests concerning all possible external aspects (figure 1) influencing the *evaluation and judgement competence*.

RESULTS

All in all, the sample of the main study included about 780 students from grade 9 and 10 of German secondary schools (Gymnasium). Due to the balanced incomplete block design each of the items in the test on *evaluation and judgement competence* and in the test on content knowledge and application of content knowledge is done by 142 students. The fit-parameters and the item difficulty of the test items are investigated by Rasch analysis. All of the items fit the criteria of quality weighted mean square value (.75-1.33) and t-value (-2.0 – 2.0) (Wilson, 2005). By using Rasch analysis, person parameters for each test are identified which can be used to investigate the relations between the tests. To find out to which degree different factors influence students' evaluation and judgement competence, correlations and regressions were calculated and path models were evaluated. While the highest correlation is between the *evaluation and judgement competence* and the application of evaluation strategies ($r = .294$, $p \leq .001$), the cognitive abilities ($r = .265$, $p \leq .001$), application of content knowledge ($r = .298$, $p \leq .001$) and the estimation of data quality ($r = -.267$, $p \leq .001$), there is no connection between the *evaluation and judgement competence* and the individual attitudes concerning environmental aspects and between the *evaluation and judgement* and social desirability. The calculation of linear regressions shows that most of the variance for the *evaluation and judgement competence* in chemistry can be explained by the ability to apply evaluation strategies in everyday-life situations ($ß = .21$, $p \leq .05$) followed by the ability to apply content knowledge ($ß = .19$, $p \leq .001$). In addition to the calculation of correlations and regressions, a path model shows the interaction between some influential aspects and fits the criteria of quality like RMSEA, CMIN/df, SRMR, CFI (figure 2).

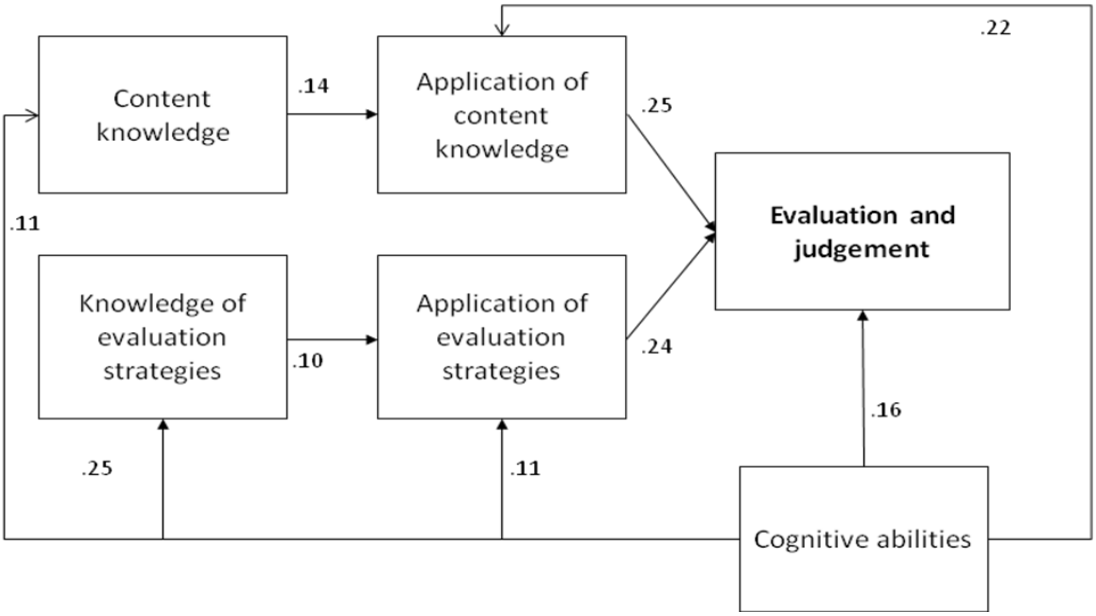

Figure 2: pathmodel for the interaction between the aspects

By using the other influential aspects in the model (social desirabilitiy, individual attitudes, estimation of data quality) the path model does not fit the quality criteria anymore. In addition to the interaction of the aspects represented in the path model, two mediation effects can be found. First the effect of content knowledge on the *evaluation and judgement competence* is mediated by the application of content knowledge. Second, the effect of knowledge of evaluation strategies on the *evaluation and judgement competence* is mediated by the application of evaluation strategies.

CONCLUSION

The data of this study provide an overview on students' *evaluation and judgement competence* in Germany. Furthermore, the study shows how the *evaluation and judgement competence* is influenced by external aspects. In summary specific abilities are needed to effect a high *evaluation and judgement competence*. One predictor for this competence is the application of evaluation strategies in everyday-life situations and in addition to that, specific content knowledge is needed. With this knowledge, students' competence can be measured, developed and trained more systematically.

PHOTOVOLTAIC AS A POSSIBILITY TO GAIN "GREEN ELECTRICITY"– A SOCIOSCIENTIFIC ISSUE TO INCREASE STUDENTS' ABILITY OF DECISION MAKING

Corinne Knittel[1] and Silke Mikelskis-Seifert[1]
[1] University of Education Freiburg, Germany

Abstract: The task of socioscientific issues has not yet been settled in German physics classes, although the National standards of science education require the implementation of such topics in class. In response to the obvious gap between educational research and daily school practice we created a teaching unit to reduce this gap. The socioscientific issue and the topic of the created unit is the use of photovoltaic to gain "green electricity". The unit contains photovoltaic experiments for students, explicit knowledge training for decision making, following the research in biology education by Boegeholz et al. (2006), and discusses the impact of this new knowledge regarding the social community. Our teaching unit aims at the increase of students´ ability to make decisions. An empirical study is conducted to evaluate the teaching unit. Due to the lack of test instruments to measure decision making processes in the context of physics, we developed a standardised questionnaire that we apply to our evaluation study. This instrument and the corresponding teaching unit were tested in two pilot studies. In October 2010 the main study has started and the data collecting ended in summer 2011.
In this paper we present the theoretical background and the conception of our evaluation study, our findings of the first and second pilot study and finally an outlook on initial findings of the main study.

Keywords: socioscientific issues · photovoltaic · teaching unit · decision making · measurement

THE STUDY

Our study consists of 2 connected parts. In the first part we developed a new teaching unit which we called PEBU. In the 2nd part our study aims at testing and evaluating the teaching unit in class. PEBU is an acronym that links at the central elements of our teaching module which are photovoltaic, energy, decision making and environment (German: Photovoltaik, Energie, Bewerten, Umwelt). The implementation of explicit decision making training into a photovoltaic teaching unit is the distinguishing mark of our new approach.
The aim of our study is to create a physics teaching unit which enables a verification of the teaching success of science knowledge as well as the competence in decision making in the socioscientific environment.

CONNECTION TO THE CURRENT RESEARCH LANDSCAPE

The National standards for science education in Germany postulate that the goal of every science class should by to develop four competencies within the "regular science teaching" (Kultusministerkonferenz, 2005). These four competence areas are: scientific knowledge, scientific inquiry, communication and decision making. Excellent science teaching practice has always aimed at unfolding these competencies, but now they become an official claim which means that there must be an implementation. This generates a lot of research concern-

ing all four competencies. However there is a gap between research and school practice. But there are studies trying to conquer this gap.
Three interesting research approaches from different parts of educational science research are presented as an example of a great variety of studies.

1. There is the participative approach used in the current chemistry research (Eilks & Byers, 2009). This approach is based on authentic and socially relevant problems which can be solved using chemistry knowledge. Due to the fact that multiple correct solutions exist, the selected solution depends upon the person that solved the problem.
2. Then there is the SSI approach established in the USA (Sadler & Donelly, 2006). This approach claims that the best contexts for decision making problems are socio-scientific issues. A “socioscientific issue” is described as a controversial social issue with conceptual, procedural, or technological ties to science. This approach is highly accepted within the community and many studies are following this path.
3. The third presented approach is the “Goettinger-Modell” (Eggert & Boegeholz, 2006) developed in German biological science education research. This structural model postulates four constituent competencies and for each of them a progression of four graduations of difficulties.

According to the above presented examples our topic of photovoltaic is extremely appropriate. Measured with the ideas of the participative approach, the topic is socially and ecologically relevant and authentic. Dealing with it demands physics content knowledge. The topic also fits into the SSI approach and the usage of the Goettinger model is extremely suitable to the study presented here, and it is therefore used as a guideline.

THE TEACHING UNIT PEBU

The content of our teaching unit is an aspect of ecological building, namely the use of photovoltaic to produce electric energy. The students will consider this specific topic from a broad perspective and discuss their findings. The goal of this unit should be to guide the students to become reflective and independent individuals which are capable of making decisions in complex situations. On one hand the students get the chance to learn the physics of photovoltaic plants by conducting many experiments and on the other hand they get in touch with economic problems like cost-benefit-analysis or social problems like the influence of press coverage on public beliefs. In addition the students are confronted with different strategies of decision making and they get opportunities to exercise these strategies in the method training and in the following lessons.

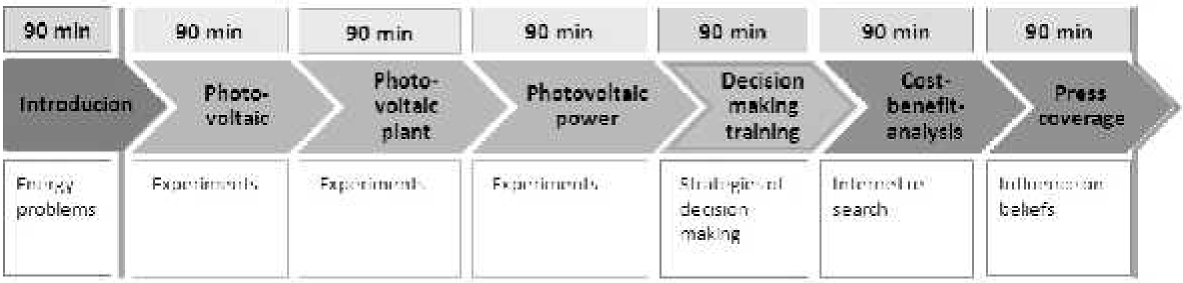

Figure 1: Design of the teaching unit PEBU

CONCEPTION OF THE EVALUATION STUDY

The following research questions build the focus of our evaluation study:

1. Is the topic of photovoltaic within the reach of students’ interest?
2. Is the teaching unit PEBU able to increase the ability of decision making?

   a. Which conclusion can be made with respect to the development of decision making competence?
   b. To which extent are the changes in decision making produced by the complete teaching unit still applied six weeks later?
   c. To what extent is the explicit decision making training able to increase the ability of decision making?
3. Can different decision making strategies be detected?

Our questionnaire entails three different parts. The first block contains Likert-Items to evaluate the students´ interest in photovoltaic and ecological building. The second block consists of several complex situations in which the students should make their decisions. These decision items are open items as they show the decision making process and the corresponding reasoning. The last block of the questionnaire is the knowledge block. It contains items to evaluate the content knowledge which should be gained by the PEBU teaching unit. We tested this questionnaire two times. The first pilot study was realised with third semester students from the University of Education Freiburg (average age of 25). The findings of this first study lead to a revision of the questionnaire and the design of the teaching unit. In the second pilot study we re-tested the new measuring instrument with 150 college students (average age of 14). Parts of the findings of the pilot studies are presented below.

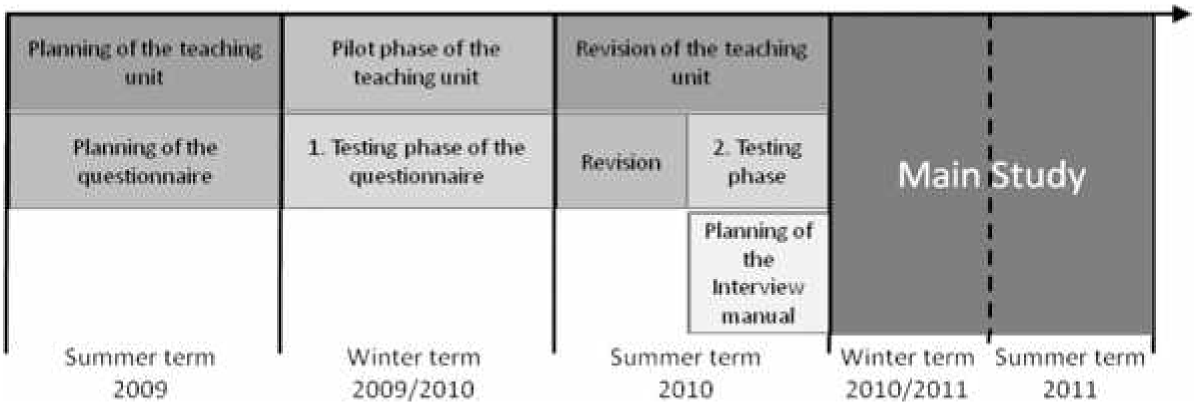

Figure 2: Timeline of the study

FINDINGS OF THE PILOT STUDIES

The first pilot study showed that the first version of the questionnaire was able to measure the teaching unit's impact students's knowledge increase. We could verify a highly significant increase of knowledge. However, it should be mentioned that the students, despite the improvement, were not able to answer more than 50% of the knowledge questions after teaching. From this followed that the knowledge improvement has not reached its maximum, and this lead to a revision of the teaching unit. The decision making block of the first version of our questionnaire contained five open questions which were treated with qualitative content analysis. The goal of this part was to evaluate the number and kind of mentioned assessment criteria as these findings are linked to the ability of understanding a complex situation and the ability of analyzing the problem from different angles. These aspects can be used as indicators for the decision making ability of the students. In the first pilot study we could not find an increase in the decision making ability. This finding is the reason for our hypothesis that it is not possible to increase students´ decision making ability by just teaching expert knowledge without discussing decision making on a meta-level.

For the 2nd pilot study, the first block of the questionnaire, containing the interest-items, remained unchanged because the results can be transformed into 4 scales of interest with good reliabilities and the second study supports the findings of the first study. The knowledge part of the questionnaire was not part of the re-testing process as the participating students tested only the questionnaire without the teaching unit. However, the results of this part of the questionnaire from the first pilot study were satisfactory. The test of the second pilot study still contains a decision making block but with even wider items. There are now four categories of decision-items. First an easy item where the situation is described and all needed information is provided so that the students only have to make the last step and decide on one of the possibilities. In the second part the sitation is described and pieces or advice of three friends are given. The student has to think of the advantages and disadvatages of every advice before he or she takes a decision. Then in the third part the situation is described and all information needed is hidden in the text so that the students have to read, comprehend and decide for one possible reaction. In the last part the situation is descirbed as well as two decisions of two other people and the students have to decide which decision making strategy is best. The pilot study detected that the third item type was too difficult for the pupils and was, therefore, changed for the main study. The other three where successful and are used unchanged.

THE MAIN STUDY

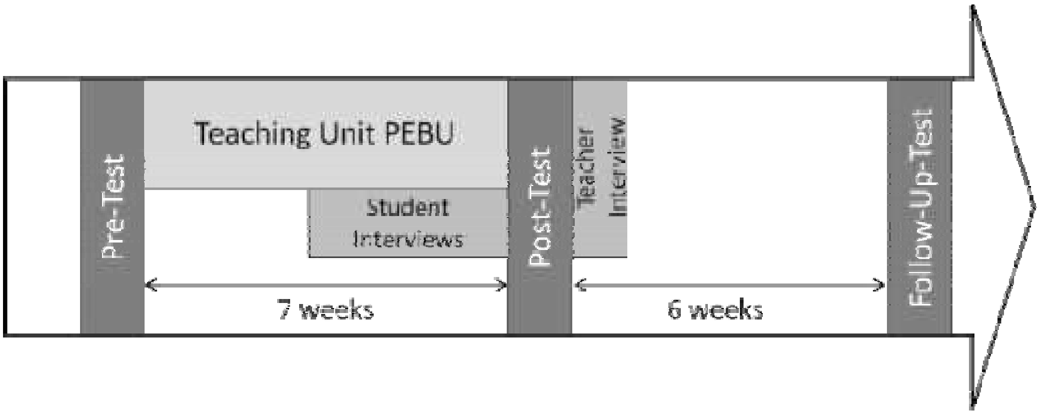

Figure 3: Design of the main study

To gain information about the decision making strategies of the participating students, we created a questionnaire which we tested and retested in two pilot studies. The first study showed, that the questionnaire is able to measure the students´ impact of knowledeg as well as the students´ interest in photovoltaic. The pilot studies caused a revision of the decision making block. Now the questionnaire contains three successful item types, which we will use in our main study.

The main study started in October 2010 and was concluded in summer 2011. The experimental group has six participating schools with approximately 200 students. The control group contains of 4 classes comprising 100 students.

The decision making competence and the content knowledge was evaluated by our tested instrument in a pre-, post- and follow-up-design. To gain additional information concerning the development of the decision making competence several students were interviewed. After the teaching unit there was an interview with the teacher to evaluate the teachers' perspective and his or her understanding of decision making in socioscientific environments.

INITIAL FINDINGS

In this paper we like to present our first answers concerning the third research question 'Can different decision making strategies be detected'. After the collection and compilation of our data we detected three main strategies of decision making. Valuation method I is an intuitively based decision, method II contains decisions which uses either the cut-off or the list of benefits their main strategy and finally people using the trade-off strategy fall in to the category of method III. This finding does not represent the whole effect of our intervention but Figure 4 shows the percentage of each evaluation method.

Difference between question type 1 and 2
The findings for question type 2 are nearly unchanged in Pre-, Post- and Follow-up-test. While the findings for question type 1 change slightly but stay clearly different from type 2. This difference is not surprising as question type 2 is clearly more difficult than type 1. This may also be an explanation for the most frequent use of the valuation method I (intuitive). In contrast, the easier questions type 1 was often solved by using a more complex method.

Change in answering type 1 questions
The used strategy for dealing with questions of type 1 changed over time in this population from demanding to more intuitive. As can be seen by comparing the shape of the bar diagram. From our point of view there are two reasonable explanations:

1. Possibility: *Fatiguing effect* by confronting the students with the same question type.
2. Possibility: *"Expert" effect* by not writing down every little step.

Application stability of the chosen method
In this population the frequency of method III question type 1 in the Pretest is surprisingly high. But in the following tests method II turns out to be the only stable solution strategy for this type. For question type 2 on the other hand the detected strategies are immediately stable, means that students do not change their strategies between the three tests.

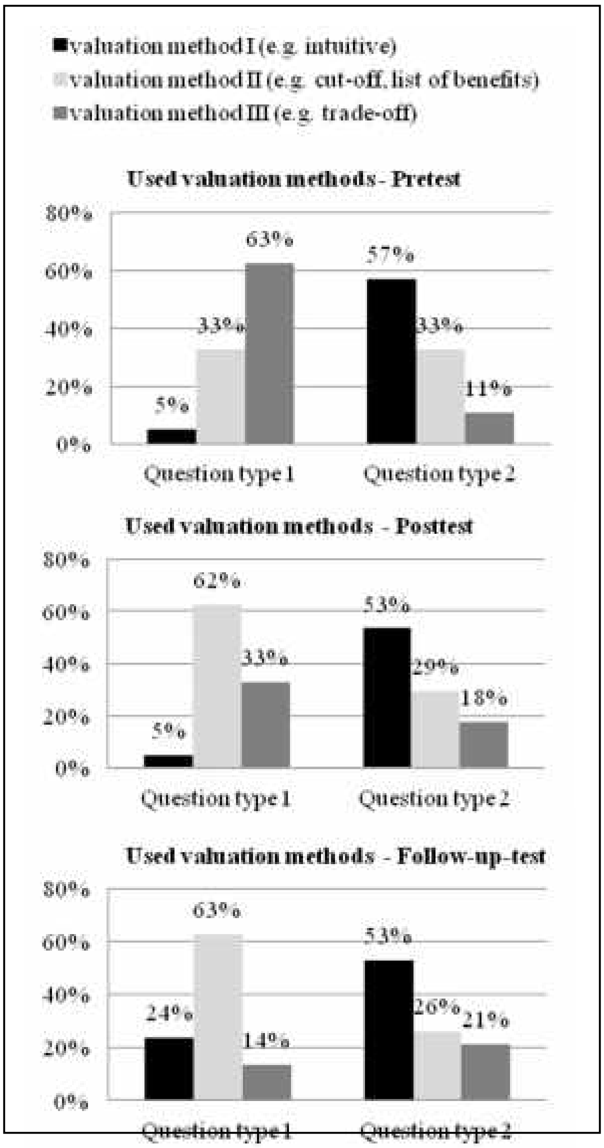

Figure 4: Detected decision making strategies (type 1: buying situation, type 2: discussion with friends)

CONCLUSION AND OUTLOOK

Our Data lead to the conclusion, that students use three different methods of decision making. The choice of method depends on the question type and the corresponding degree of difficulty. The more complex the question gets the more basic the chosen method. If the question type is demanding then the choice of the method is very stable. For simple questions type 1 (e.g. buying decisions) we observe a decrease of the use of complex methods. This observation may be caused by either a fatiguing or an "expert" effect.

In our further research the combination of our different sets of data will be used to answer the research question 1 and 2. The second question will be the challenging one as the data suggests there is a strong relationship between the chosen decision-making strategy and the given context. This important connection, however, is not part of our guiding structural model, the

“Goettinger-Modell”. The main task is therefore to advance the given model to analyze the possibility of increasing students´ ability of decision making within the teaching unit PEBU.

Abstract : Education for sustainable development differentiates itself from the customary educational situations. The challenge is not only to adapt social issues to a school context but also to participate in collective experiences of development according to a mission of implication and of preparation of the actors for their role in society. Educational actions, like collective experiences, fulfill the requirements for the incorporation of *dispositions* – attitudes, abilities, beliefs - (Bourdieu, 1998) for choosing, for deciding and for acting. But an education focussed around “dispositions” transforms evaluation for researchers and practitioners. Thus, having indicators becomes a strong challenge and we then need to have a theoretical model of the commitment in action. For instance, H. Joas (1999), about the human action, distinguishes intentionality, corporeality and social instincts. Evaluating the changes in pupils ‘attitudes and commitments requires from the teachers to have indicators enabling them to take those distinctions into account. This contribution aims at discussing the functional organization of selected indicators. This prospective work has been established thanks to pieces of data collected from three projects conducted in primary and secondary schools during three years.

Keywords: Education for sustainable development; curricular approach; educational action; educational indicators

This article has been translated into English by Marie Vergnon,
This work has received the financial support of: INRP and ANR (ANR-08-BLAN-0135-01)

BACKGROUND AND PURPOSE

The idea of Sustainable Development (SD, below) requires that we collectively work a development out which takes into account environmental, social and economic issues raised by social groups to the conflicting interests (Aubertin and Vivien, 2006). SD induced in itself or through its fundamental principles, such as the precautionary principle, the willingness to anticipate a better evolution of human societies in an enlarged temporality with the goal of controlling the future. This is a progressive and irreversible process: a broadening of the field of the political action, not only to the human being as a species, but to the entire biosphere (Doron, 2009). In France, in relation with the recommendations policies such as those of the commission chaired by Brégeon (2008), two missions for compulsory school (School, below) may be defined: a mission of participation and a mission of preparation of actors to the dynamic of transformation of society. The challenge for School is not only to adapt some socio-issues but to allow the participation of pupils to collective experiences like a real and repeated “educational action”. "Educational actions" indeed enable the incorporation for “dispositions" initiating deep tendencies to choose, to decide and to act now and later (Bourdieu, 1998). “Dispositions”, means the whole of standards, attitudes and beliefs which encourage people to act or inhibit them. These dispositions are the central point of these educational situations (Lange and Martinand, 2010) and may be the subject of learning. Thus, the current participation in actions to SD prepares the actors thanks to the constructed “dispositions”.

RATIONALE

The choice of effective actions of SD as an educational modality requires the development of new strategies of evaluation: it cannot be one of the customary modalities of evaluation of knowledge or a *skills* assessment through observable *performances.* Indeed, who could judge a performance of sustainability? Various works under the aegis of the UNESCO, have proposed some general principles for the development of indicators. In agreement with Rode (2006), three levels should be distinguished: a "macro" level or level of educational policy, the target of works managed by UNESCO, a "meso” level of educational institutions, a "micro" level for the class or for the educational project. Our work aims at developing "micro" and “meso” indicators allowing an assessment and regulating “educational actions”. Having indicators is necessary both for the teachers as an indication of the supports and obstacles exist with learners, and for the actors (teachers and pupils) of the project as a way to evaluate, and to regulate the action. These indicators can be divided into three categories as follows: sustainability, suitable knowledge and incorporated dispositions. But these dispositions are not observable. How then render an account of it? How to make them operational linking them with objective criteria?

The subject of this contribution is to identify indicators that can be observed or collected through the speeches and aims the empowerment of the actors involved in the project of ESD in order to enable them to make choices as to strategies.

METHODS

Coming from the field of sociology, the idea of indicator proposes to develop observable variables to account of a reality not noticeable immediately. We can thus distinguish between: indicators, lists of indicators, aggregated indicators or index (Boulanger, 2004).

Aggregated indicators, or index, are a tool for the evaluation of public action for public use and may become the privileged instrument of an active and critical democracy in allowing the perception and understanding of the externalities. Finally, our project is to develop a qualitative index of the efficiency of educational actions of SD.

A synthetic index is built in several stages (Table 1).

Stage	**Characteristic**	**Objectivity/Subjectivity**
Identification of scientific concepts	multidimensional	In principle objective
Selection of relevant variables	Qualitative, quantitative, semi-quantitative	Objective but choice in view of the project
Measures	Determination of scales, the degree of precision, the thresholds	Objective but elements of subjectivity in choice
Operational	Synthesis : single index	Step the more subjective and more contested

Table1: Stages in the construction of an index (from Boulanger 2004)

Incorporating the approach proposed above, this work was carried out in three times:
- Meta-analysis of the theoretical corpus concerning the theories of action (Baudoin, J-M. and Friedrich, J., 2001).
- Selection of the theoretical framework according to a principle of consistency, and then the development of a theoretical framework
- Empirical validation of the feasibility in the third level in primary school, the lower secondary school, and the first level of the higher secondary school, in the existing institutional framework. This step is the result of placing in correspondence with the categorizations carried out in a previous study (Lange et al, 2010) by means of a content analysis (Bardin, 2001) of the students’ speech.

In a first step three projects carried out in primary and in secondary schools have been followed. We have chosen to place ourselves in three levels of the general and compulsory education, in a comparative standpoint which characterizes a curricular approach: the third level of primary school, the lower secondary school, the first level of the higher secondary school, in the existing institutional framework. The works presented here are only one of the issues raised in a search package aiming at developing a theoretical framework to think out a “possible curriculum” of the ESD. The highlights of the projects are more particularly defined and interviews are beforehand carried out with the pupils on the basis of volunteerism, and then according to projects. The technique used is this of a semi-directed interview which follows a guideline adapted according to the level of the class and the moment of data collection. The analysis of contents of the students’ speech has helped us to determine three sets of item.Thus, are taken into account, the report to the action, which is central in the strategy established by our work, the relation to the other and the involvement in the social fabric, the relation to the world.

RESULTS

Development of a schema of commitment

The implement of an action of SD requires on the part of the actors some forms of coordination. It results from the special mobilization of external and internal support to the subjects, in a conscious and an unconscious way.
Their inventory and their parameterization (Dodier, 1993)[1] is a necessary prerequisite for any research on this issue. However, supports can become obstacles according to the schemes of coordination desired or desirable: the schemes of coordination are in fact oriented by the missions institutionally prescribed or self-prescribed by the actors themselves. These schemes are dependent on external support, resources and constraints, and internal support to the acting subject.
The internal support exists in the form of a capacity already present but prone to transformation through reflexivity. We assume the presupposition that any experience carried out by an individual develops in him some “dispositions” (E. Bourdieu, 1998). These dispositions constitute the basis which determines the intentions, the choices, the decisions and the way of acting of individuals. But the dispositions are not observable.
In a search for coherence in the references to be used, we look to the pragmatist philosophy. In a postmodern and pragmatist approach, Hans Joas insists on the creativity inherent in “human acting” (1999). Indeed, for Joas, this deep characteristic of human being is revealed in the confrontation with crisis situations. Beyond the speech, it’s about commitment and intentionality which he is talking about. Thus, for this author, thinking of the “human acting” comes to distinguish between intentionality, corporeality, and sociality which for their part are observable. He thus makes distinctions which allow us to think of the intention of commitment and action of the subject. These parameters result for their part of the underlying trends, or “dispositions”, of individuals.
The external supports, for their part, are linked to the situation, the material conditions and institutional realization. In the case of an action of ESD (AESD), those are the effects of territorial, institutional and media (exhibitions, local associations …) contexts. But beyond the support, these contexts affect the whole of the situation through the repercussions that they have on the identity of the actors themselves.
Two extreme forms of coordination are then possible depending on the internal and external supports existing. If the forms of coordination between teachers have been the subject of recent studies (Grangeat and Coquide, 2010), the AESD require the involvement of the whole of the "stakeholders" of the action of SD enterprises (Lange et al, 2010). A term to term correspondence may be established.
The first one is minimalist. It requires only a multilingual and instantaneous comprehension and depends on the situation. In the case of the ESD, it corresponds to the modality of "teaching" and not “educate”, including that of the co-disciplinarité, i.e. an *additive form*. The second one is Maximalist. It’s based on the sharing of judgment of universal value and the need of judgments, or shared "reasoned opinions", deliberations, of arguments, returns on oneself explicit by the language. In the case of the ESD, this extreme form corresponds to what we have designated under the word AEDD. The most sophisticated form, or *co-active form,* is based on two skills of the actors: their capacity to get involved in the coordination and their capacity to adapt to the change of forms. They characterize the establishment of a "learning community" (Kalubi, 2005), and "research community". (Lipman, 2006). Being non-spontaneous, it requires a specific learning.
Between these forms, an intermediate form, called *completive form*, is possible.

[1] Dodier’ s work is based on the work of Boltanski and Thévenot (1990)

The schema below is adapted from a model developed by Godin (1991) from a work carried out in Psycho-sociology about education in health that was reprocessed - with pragmatist references. Unlike the work of Godin, the aim here is not a behavioral change but the commitment of the actors in a collective action of DD. This schema is a synthesis and puts into perspective all the parameters.

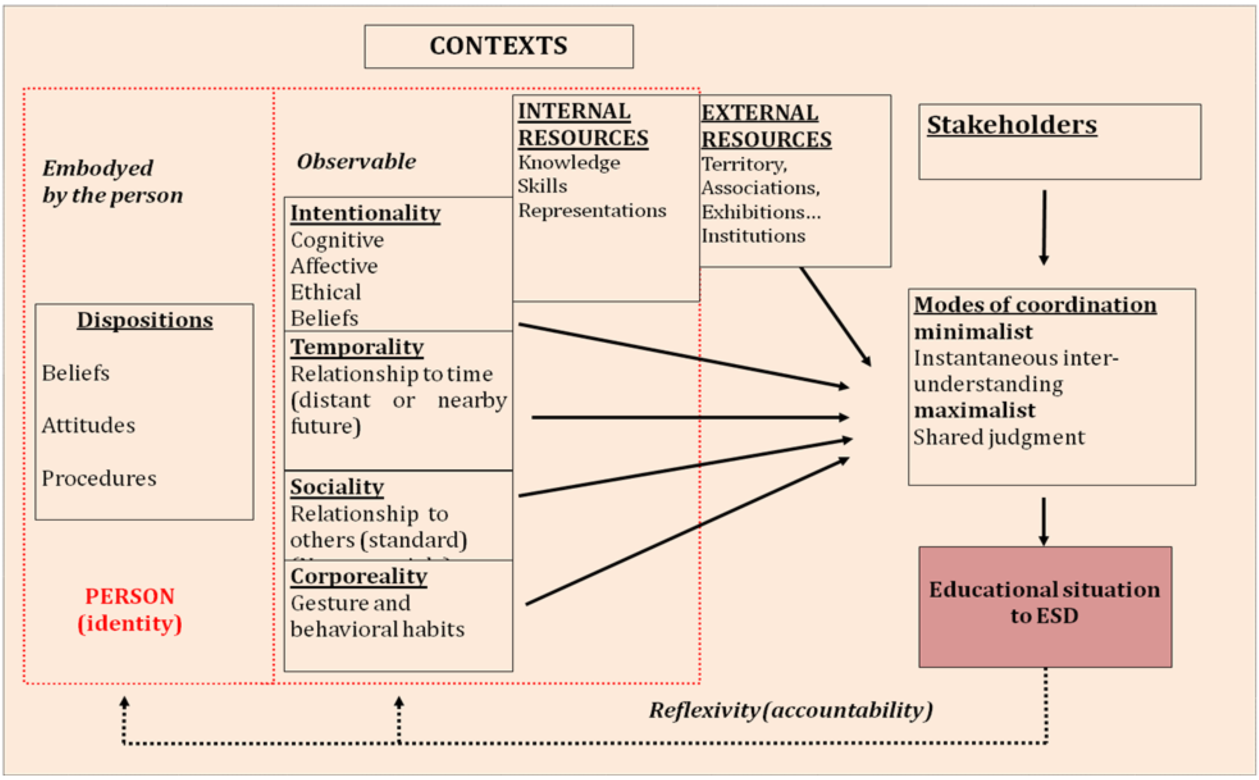

Fig. 1: parameters of engagement

Determination of the indicators

The analysis of contents performed previously allowed us to select a number of items. It constitutes the foundation for the development of qualitative indicators of ESD (Lange et al, 2010). It remained to clarify the relationship between these items and the determinants of the collective commitment in an action of SD to establish indicators. Empirical confrontation to their usage helps us to assess their relevance and efficiency. We propose the following list:

- Indicators of internal resources mobilized by the person
- Relationship to knowledge *(as part of the culture; as a tool for the analysis; such as support for the action)*
- Complex thought and "multireferentiality "*(simple opinion; developed opinion; reasoned opinion)*
- Relationship to Nature *(subject, resource, project)*
- Relationship to science and technology *(rejection, such as a solution (low sustainability); part of the questioning and solutions (strong sustainability))*
- Relationship to the other *(the other as support, the other as obstacle)*
- Skills in real situation

- Indicators of intentionality
- Appropriation of the challenges of the DD. *(convinced active; confident self; responsible)*

- Acceptability at School of the ESD *(rejection; indifference; accession)*
- Acceptance of the constraints *(inhibitory; accepted)*
- Level of participation in the project *(running, participation in exchanges, participation in the development of the project)*
- Level of involvement in the action *(passivity, unreasoned impatience to act ; desire of collective action; in the reasoned action)*

- <u>Indicators of temporality</u>
- Temporality of the proposed action *(immediate, delayed, postponed on other generations)*
- Perception of vulnerability *(naïve catastrophism ; enlightened catastrophism)*
- Appropriation of a spirit of solidarity *(extended to non-humans and to future generations or not)*

- <u>Indicators of sociality</u>
- Ability to perform transfers *(family; territory of proximity; worldwide)*
- Appropriation of the SD as a new social norm

- <u>Indicators of corporeality</u>
- Direct indicators *(actual observed gestures and behaviors)*
- Indirect indicators *(induced effects on consumption, production of waste, usages of devices)*

- <u>Indicators of forms of coordination</u>
- "Additive" form *(ESD in classroom and customary courses)*
- "Completive" form *(Community of practices among teachers)*
- "Co-active" form *(establishment of a learning and research community, focused on the education team, opened to stakeholders)*

OUTLOOK

We now have a schema of the commitment in the action, available to query the situations of education for sustainable development and a set of qualitative and quantitative indicators of the operational efficiency of these actions. Making them operational for the class requires integrating them in the form of an index describing the profile of the student,

We intend to use the idea of "agent", "actor" and "author" mentioned in the literature (Lange et al, 2010). Let's make clear these words by using an analogy adjournment of the didactic of the physical education and sport, a didactic of a creative action, and in particular the work of Mrs. Romain on the dance of creation "dancer, spectator, choreographer". The analogy is based on the fact that an ESD project is a creation without constant renewal in which the teacher masters the intention and the educational aim but in which he knows neither the possible solutions nor the way to perform. They co-construct the whole of the experience. We can distinguish, the "agent" who is behaving like a subject in the school system or a simple performer, the "spectator" who is on the intellectual side of the case; the "activist" who is anxious to act in favor of the SD and the "author" who combines in harmony making and saying, the action and the speech. This profile corresponds to the high ideal expected type, and becomes the referred educational for a curriculum for the ESD.
At this stage, we have a grid of indicators of the operational efficiency of the ESD and are now looking to develop a tool for the actors of the ESD (educators/learners) in the form of synthetic indices, the index, capable to account for the dynamics among the students, and

therefore to accompany them, thus including the actions of SD in an sustainable educational process.

PONDERING DEBORAH’S DILEMMA: ASSESSING RISK IN SCIENTIFIC ISSUES

Ralph Levinson[1], Phillip Kent[1], David Pratt[1], Cristina Yogui[1], Ramesh Kapadia[1]
[1]Institute of Education University of London, U.K.

Abstract: Risk has now become a feature of science curricula in many industrialised countries. While risk is conceptualised within different theoretical frameworks the predominant model used in examination specifications in the United Kingdom is a utility model in which risk is deemed to be objective through technical expert assessment, and where the perceptions of individual actors can be corrected by appropriate rationalisation of action and thought. However, research studies on heuristic reasoning and public decision making concerning risk-based issues in science demonstrate that a utility-based approach fails to take into account social, experiential and cultural factors which frame what is considered to be risky. Our research study with science and mathematics teachers deploys a microworld, „Deborah‟s dilemma‟, which presents a decision-making scenario involving probabilistic estimates where teachers construct their personal models of risk. Teachers were recorded in dialogue while working through the microworld. Inductive coding of the dialogue and interactions with the microworld shows that teachers‟ decisions on risk have a rational underpinning but that use of data and information only becomes coherent and comprehensible within the explicated values of decision-makers. We suggest that designing programmes on learning about risk in science must incorporate the opportunity to make values explicit in concert with developing understanding of probability and other factors.

Keywords: Risk, values, curriculum, decision-making

BACKGROUND, FRAMEWORK AND PURPOSE

In 2000, in the wake of crises such as BSE, Chernobyl and salmonella egg poisoning affecting international agriculture and nuclear industries, the House of Lords Science and Society Committee noted that „When science and society cross swords, it is often over the question of risk.‟ (http://www.publications.parliament.uk/pa/ld199900/ldselect/ldsctech/38/3806.htm#a37). Such policy responses which have led to arguments for the inclusion of risk assessment and evaluation in U.K. curricula (Millar and Osborne 1998) reflect public anxiety in developments in science and technology in late modern societies in what has become known as the Risk Society (Beck 1992). Risk is now included in the national curriculum in science in England as well as other industrialised countries. While there have been cogent epistemological justifications for the inclusion of risk as a topic in the science curriculum (Ryder 2002, Christensen 2009) and empirical studies on students‟ understanding of risk assessments (Eijklehof 1990, Kolstø 2006, Gardner *et al*. 2010) there has been no developed theoretical framework in science education which draws on the social, cultural and psychological literature underpinning the teaching and learning of risk. Risk is now covered extensively in examination specifications in England where the predominant model of risk is a utility approach. The purpose of our study was to design a decision-making scenario co-ordinating elements of probability and outcome in an authentic event involving risk-based decisions which would enable us to examine experiential and personal constructs of risk.

RATIONALE

If there is such a thing as „actual‟ risk, or a range of situations when objective risk can be depicted, then teaching needs to focus on utility and rational approaches to defining and solving risk problems, which might take into account popular perceptions of certain unlikely events (Slovic 1987). For example, the Salters-Nuffield Advanced Biology textbook (Hall *et al*, 2005) defines risk as „the probability of occurrence of some unwanted event or outcome‟ (p.20) and that „[P]eople frequently get it wrong, underestimating or overestimating risk‟ (p21). Our research involving science and mathematics teachers who would be teaching about risk was to explore how teachers construct concepts of risk and what faculties and domains of experience they draw upon in discussing how to make a decision in an authentic risk-based scenario.

METHODS

We developed a scenario, Deborah‟s Dilemma, in which three pairs of mathematics and science teachers considered the dilemma faced by a fictitious person (Deborah) about whether to have an operation that could cure a spinal condition that was causing her considerable pain. Teachers were encouraged to put themselves in Deborah‟s situation. Having the operation would be likely to result in a complete cure but would entail certain hazards which would need to be discussed by the teachers from various sources of information. Choosing not to have the operation would result in Deborah/the teachers managing her/their lifestyle(s) through daily routines of work, domestic and leisure activity, in order to alleviate the ongoing pain resulting from the medical condition.

Information about Deborah‟s condition was set out within the software <www.riskatioe.org> in a deliberately personal way, to offer different perspectives with varying levels of authority. Two software tools accompany the information about the condition. The first (*Operation Outcomes*)

(Figure 1) is a probability simulator in which the teachers modelled the possible consequences of having the operation. The likelihoods for these various complications (i.e. side effects of the surgery, ranging from minor to serious, and even death) were quoted in the information provided in differing forms and from conflicting, sources. The teachers were required to draw on the sources and decide which possible complications to incorporate into their model with what they considered to be appropriate probabilities of the operation‟s success. Hence the teachers created their own model as an interpretation of the complex information provided.

Figure 1: Probability simulatorOperation Outcomes

The second tool, the *Painometer*, (Figure 2) is a less conventional attempt to give a quantified experience of Deborah's pain and how different activities may cause it to increase and decrease, relative to a “tolerable” level where the personal perception of pain is a potentially interesting context for probing people's personal models of risk. The teachers were required to decide what activities Deborah should or should not do and to infer from the information the effect on Deborah‟s pain level due to those activities.

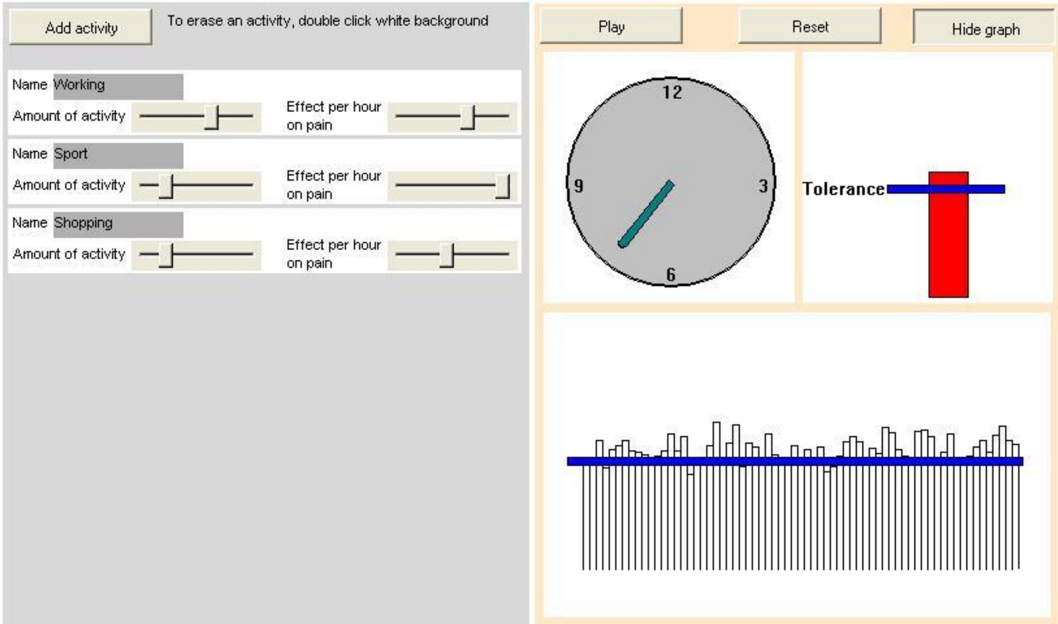

Figure 2: The painometer used to model Deborah‟s lifestyle

The teachers were able to control Deborah‟s level of pain tolerance, the amount of work and domestic/leisure/sport activity that Deborah does and the pain intensiveness of each, assuming that some types of work and sport would worsen the pain and others would relieve it. It was also possible to introduce new activities such as shopping and yoga into the model of lifestyle with the aim of looking to see if a balance could be achieved between pain-inducing and pain-relieving activities, so that Deborah might achieve a tolerable amount of pain from day to day.

The teachers (one science and one mathematics practitioner from the same school in each pair) worked through *Deborah's Dilemma* to consider the options and what decision they might take were they in her shoes. A researcher sat with each group but only intervened to demonstrate relevant aspects of the software, to address any technical points and to ask questions for clarification. Having arrived at a decision, each pair of teachers wrote a report explaining their reasoning. Video screen capture software recorded the process of decision-making through the teachers‟ dialogues and manipulation of the simulators. The session lasted approximately 2 hours. Data for the analysis consists of an audio transcript for each pair of teachers, a video record of their interactions with the software, their written account of the reasoning behind their final decision and notes from each researcher including observations from a „floating‟ researcher who was able to compare the inference-making of each pair. Team members inductively derived themes from the transcripts which were iteratively negotiated.

RESULTS

The following themes emerged from analysis of the transcripts.

i. Five of the six teachers decided that the operation was worth having even though there was a 1 in 200 chance of serious harm resulting from the operation.
ii. All three groups of teachers were critical of sources of data even though they were prepared to make decisions based on probabilities which they were ambivalent about.

iii. Following from ii teachers tended to trust medical/scientific authority even though they realised the source of this data had uncertainties associated with it. While teachers" trust of expert opinion reflects that of students in Kolstø"s work (2006), the difference is that the teachers understood in a sophisticated way the limitations of scientific expertise and the uncertainties associated with it.

iv. Teachers" assessments of risk were made in the context of their personal, experiential and social values which they explicated. Considerations of probabilistic estimates and changes in lifestyle could only be explained and understood in these terms. At best judgments based on probabilities were post hoc rationalisations of value considerations.

v. Teachers provided justified and evidence-based reasoning throughout the decision-making process but their decisions did not necessarily follow from reasons given. Teachers" constructions of their personal models of risk incorporated both rational assessments and values based considerations.

vi. Teachers rarely co-ordinated probabilistic estimates of the operation"s success with changes in lifestyle and did so only on prompting.

CONCLUSIONS AND IMPLICATIONS

Our analysis suggests that the utility approach to teaching risk provides only a partial understanding of the social and individual complexities involved in making risk-based decisions. Two pedagogic implications emerge from our work: a. while an understanding of probability might aid making risk assessments this presupposes values explication. This is a crucial challenge for teachers but one that pupils are likely to respond to. b. Co-ordinating probability with considerations of impact or alternative courses of action needs to be made explicit in any teaching and learning model of risk. We have therefore incorporated a feature in the Deborah"s Dilemma microworld which allows this co-ordination to take place.

TURKISH SECONDARY SCHOOL STUDENTS' VIEWS ON SOCIO-SCIENTIFIC ISSUES: RESOLUTION REQUIRES ACTION

Fatih Çağlayan Mercan[1], *Buket Yakmacı-Güzel*[1], *and Füsun Akarsu*[1]
[1] Bogazici University, Turquey

Abstract: This study examines Turkish secondary school students' informal reasoning in the context of responding to three dilemmas on socio-scientific issues (SSI). A qualitative methodology was adopted to attain a deeper understanding of the students' informal reasoning. Data collection involved having the students respond in writing to two of the three dilemmas followed by group interviews. The participants were 36 students (22 male, 14 female) at grade 10 (age 16). Data were analyzed using constant comparative method to identify themes in the participants' arguments. The emerged themes were action, agents of, types of, reasons for, and the tone or attitudes towards action. Most of the students lacked scientific knowledge on the SSI dilemmas, yet considered the dilemmas not as technical but as ethical problems, having their roots in human nature, manifested by the actions of individuals and governments. The students viewed human nature as extremely individualistic and hence must be regulated by a higher authority such as the government. For the students, individuals and governments are not sincere in their efforts related to SSI, leading to doubt; human nature will not change, leading to despair about the possibility of solving the SSI dilemmas. The results imply that students do not need huge amounts of scientific or philosophical knowledge to engage in SSI discussions. The results also imply that for science education it may be meaningful to focus not solely on epistemology but also on ethics and politics as well.

Keywords: Socio-scientific issues, global warming, Turkish secondary students

BACKGROUND, RATIONALE, AND PURPOSE

Preparing scientifically literate citizens who are able to participate in decisions is stated as one of the major goals of science education (OECD, 1999). The class of decisions that await citizens such as genetically modified food, energy choices, and managing natural resources are called socio-scientific issues (SSI), which are often controversial, ill-structured, and lack clear-cut solutions (Sadler, 2004). Reasoning about SSI, often conceptualized as informal reasoning, usually involves making value judgments by coordinating scientific knowledge with ethical and personal concerns (Sadler & Zeidler, 2004) as well as by considering economic, political, legal, or religious factors (Barab, Sadler, Heiselt, Hickey, & Zuiker, 2007). Based on the nature of informal reasoning, it is reasonable to expect that value judgments and personal considerations are influenced by the society and hence vary from one cultural context to another. However, much of the science education research about informal reasoning has been conducted in Western Europe (Ekborg, 2008; Lewis & Leach, 2006) and the USA (Barab et al., 2007; Sadler & Zeidler, 2004). Few studies have explored informal reasoning in the context of SSI in a developing country such as Turkey.

Studies in Australia (Boyes, Skamp, & Stanisstreet, 2009), Spain (Rodrigues, Boyes, & Stanisstreet, 2010), and Turkey (Kilinc, Boyes, & Stanisstreet, 2011) with secondary students on global warming and energy issues were mostly concerned with individuals' beliefs about usefulness of specific pro-environmental actions and their willingness to undertake those actions. For direct actions such as paying more for low energy appliances the willingness to act was more than the belief in usefulness of the action for all three countries. On the other hand, for direct actions such as paying more for electricity generated in nuclear power stations and using public transportation, and for indirect actions such as voting for environmental taxes, legislation, or international cooperation, the belief in usefulness of action was more than the willingness to act. These results were interpreted by the perceived cost of the disincentives and the benefit of the incentives: when there are incentives, such as spending less on your electricity bill and the disincentives are of small inconvenience, the students expressed that they were willing to take action; when the incentives are not that important, and the disincentives are of considerable inconvenience students were not willing to act. However, because the research was based on close ended instruments the reasons for the willingness to act was not explored. Similarly, it is possible that students do not understand the consequences of taking or failing to take pro-environmental actions. For example, Andersson and Wallin (2000) found that 15 year old Swedish students supported a drastic reduction in carbon dioxide emissions, but failed to understand the fundamental social impact of it. Students views on the ethical and political aspects involved in SSI remain to be explored.

The purpose of this study was to explore Turkish secondary students' views on SSI and the reasons for holding those views in the context of responding to SSI dilemmas. With this purpose, this study focuses on the content of the students' arguments, not on their form.

METHODS

The Research Setting and the Sample

Until 2010 students in Turkey were making the transition from primary to secondary education based on the results of a series of central standardized exams called Level Determination Exams (SBS) that students take at the end of the grades 6, 7 and 8. About one million students were entering the SBS every year and were placed to various secondary education institutions according to the ranking of their exam scores (MoNE, 2007). The secondary schools in demand are usually described by the percentile ranks of their students in SBS. The school that this study was conducted was in Istanbul and accepted students whose ranks were above the top 5% at the SBS for the year 2010 (MoNE, 2010). The school's achievement in transition to higher education is high; 80% of the graduates of 2010 were placed in a higher education institution. In the school the cohort of grade 10 (age 16) students had about 120 students in four classes. The teachers and administrators in the school stated that the classes at grade 10 were similar in terms of achievement, which was taken as an indicator for the homogeneity of the group in addition to the students' SBS scores. Two of the four classes were selected, from which 36 students (22 male, 14 female) volunteered to participate in the study. Although these selection issues suggest that the results should be interpreted with caution for generalizing to the population of all students in Turkey, they also match the requirements for the purposeful sampling for this study which seek to understand the views of high achieving students who are also articulate about expressing their views on SSI.

Data Collection and Analysis

To attain in-depth understanding the data was collected through a writing task involving three SSI dilemmas followed by group interviews. The SSI dilemmas were about energy crisis, global warming, and water taxation. The participants were given 90 minutes to respond in writing to two of the three dilemmas. Afterwards, the participants were grouped with respect to the dilemmas they have answered, and nine groups of four participants were formed for interviewing. The group interviews were conducted in a quiet room at the students' school and mediated by two researchers, with the dual purposes of giving the participants a chance to clarify their written responses and to interact with the other participants. Each group interview session lasted about 40 minutes, audio and video recorded, and was transcribed verbatim for further analysis. During the group interviews the participants were given back their written responses, then for each dilemma they summarized their ideas, and then the participants talked to each other, discussing, asking questions, challenging, or supporting others' arguments. The researchers also contributed to the discussions by asking clarifying questions when appropriate.

The data analyses involved cyclic processes of data reduction, data display, and conclusion drawing/verification, which are characteristics of qualitative analysis (Miles and Huberman, 1994). All transcripts were imported to the qualitative analysis software ATLAS.ti to manage and organize the data as well as to keep track of the analytic progress. Data was reduced by coding in which the bulk of the dataset was condensed into analyzable units by creating categories from the data utilizing constant comparative method (Glasser and Strauss, 1967). The transcripts were read line by line and open coded independently by the two researchers, and then these open codes were compared and discussed. Overlapping codes were identified, and similar codes were merged under common names, and finally the open codes were structured around general categories. The criteria for validity for the analysis were based on convergence, agreement, and coverage by the researchers (Gee and Green, 1998). The resulting conceptual themes were derived with the consensus of the researchers.

RESULTS

As the result of the data analysis, the following themes emerged: action, agents of, types of, means of, and reasons for action, and the tone or attitudes towards action (see Figure 1).

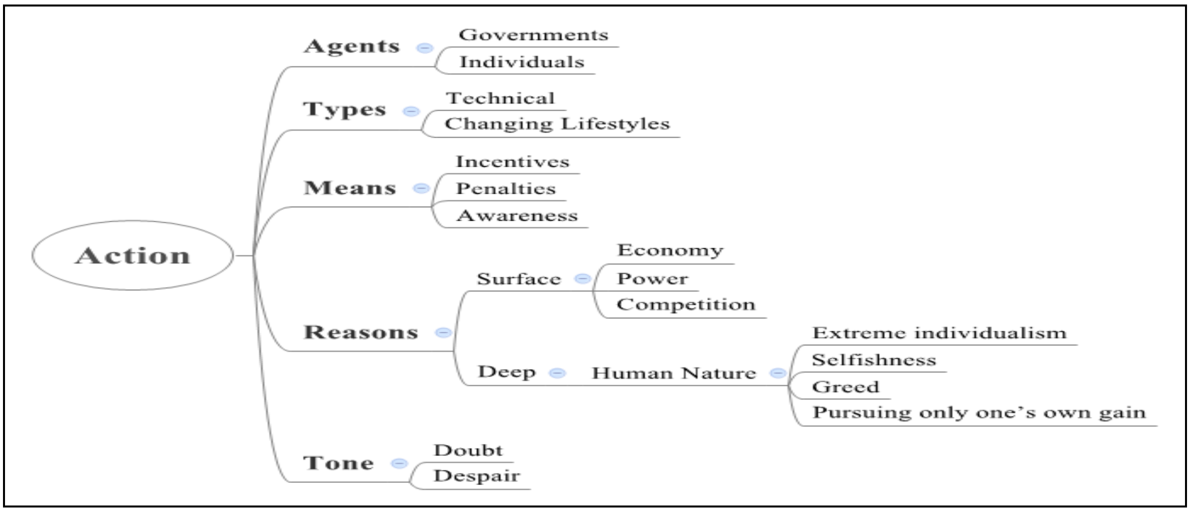

Figure 1. Themes emerged in the context of the SSI dilemmas.

Most of the students stated that they did not possess adequate scientific knowledge about the SSI dilemmas. Nevertheless, the students responded to the SSI dilemmas either positively, signifying that the dilemmas could be resolved, or negatively, suggesting that the dilemmas could not be resolved. In either case, resolution or lack of it was determined solely by acting or failing to act. For instance, according to the students the resolution of the global warming problem depended solely on the governments deciding to reduce carbon dioxide emissions and acting resolutely on these decisions. However, most of the students said that such a decision was not likely and hence it will not be acted on.

Agents of action

According to the students, the required actions for resolving the SSI dilemmas would have to be taken by governments or individuals. The majority of the students stated that individual actors could not change the world; it was mainly the governments' responsibility to take action for the SSI which they often failed. For instance, some students argued that regulating water consumption was beyond the individual and the government must act and intervene with water consumption by passing a water tax bill. The students who said that individuals may have some influence on reduction of water consumption, nevertheless, expressed that the water consumption issue cannot be resolved solely by individual efforts but by the government's action, educating the citizens, launching advertisement campaigns for water conservation, or encouraging the citizens to adopt new technologies that reduce water consumption by offering incentives.

Types of action

According to the students, there could be two types of action for resolving the SSI dilemmas: interpreting the problem as a technical one, it could be developing new technology or perpetuating existing technologies; or interpreting the problem essentially an ethical one, it could be changing people's ways of living. For instance, some students stated that the energy crisis could be resolved by developing new energy technologies that provide clean and abundant power. Other students who thought that the energy crisis is an essentially ethical problem and not a technical one argued that the resolution was independent of the amount of available energy, resolution can only be possible through fair distribution of energy, only if people are thoughtful about not only themselves but others as well, and wanted to share the resources they have with others in a just way. According to these students, the resolution was only possible by a profound change in ethical considerations and also by adopting a new lifestyle based on sharing responsibility towards all people on Earth. However, these students did not find it likely; the countries that are rich in energy resources would not agree to share their resources with other countries.

Means of action

The students suggested three ways as means for action including providing incentives, enforcing penalties, and creating awareness in relation to both types (technical and lifestyle changes) of action. The incentives could be in the form of tax reduction or exemption, low or no interest loans, or some other benefit for the people to adopt new technologies or change their lifestyles. The penalties are often stated as monetary fines, but some students also offered further sanctions including imprisonment, depending on the issue at hand. One of the common measures that the students offered as a means of action in the context of the water taxation issue was introducing a fine for overconsumption. Creating awareness in the public required providing explanations for the rationale behind the proposed actions and the possible benefits for the people. Some of the students offered education and especially voluntary participation in education as a way of creating awareness. Reflecting on their own experiences, some students said that they have changed the ways they behaved after participating in educational events such as conferences. However, some students objected to the possibility of changing people with education, according to these students it was mainly a person's conscience that guided her behavior of complying with the proposed measures for resolving the SSI.

Reasons for action or no action

According to the students, there were two classes of reasons, surface and deep reasons, for the governments and individuals taking or failing to take action. 'Surface reasons' refer to the arguments for actions at societal, governmental, or intergovernmental levels. Fear of an economic crisis, the race for power, and competition for resources are stated as the surface reasons. For example, on the surface reasons behind the lack of taking action for global warming a student said:

> The developing countries are actually acting rational when you look from their perspective; they should not listen to it. Because when these countries reduce the carbon dioxide emissions they will fall behind. (G9.S03).

'Deep reasons', the underlying reasons, essentially articulated as extreme individualism, stem from immutable traits of human nature, manifested by selfishness, greed, and pursuing only one's own gain. Human nature does not allow for action not in favour of one's own gain, unless the peril is immediate. Therefore, the SSI dilemmas essentially cannot be resolved, unless individuals and their human nature are regulated by a higher authority such as the government. For example, on deep reasons underlying the global warming issue during a group discussion some students said:

> S31: This one is also selfishness. The very same thing with the energy crisis.
>
> S17: Because people are the same. Everyone only thinks about himself. They should think about the human race. But it just isn't like that, people are selfish. If they keep acting like this there won't be a solution. We can never solve this problem.
>
> S17: They have been living like this for centuries. They will never change (G4).

Tone or attitude towards action

The general tone of the students' writing and talk on the SSI dilemmas was marked by either doubt or despair. The students did not seem to believe that the governments and individuals were sincere in the efforts for taking action to resolve the SSI dilemmas. The students thought that individuals' decisions and actions could not contribute so much to resolve the SSI dilemmas and the governments always had hidden agendas, hence these students expressed that they doubted that SSI dilemmas could ever be resolved. Similarly, some of the students appeared to have completely lost faith for even the possibility of resolving the SSI dilemmas. According to them, governments and individuals were self-serving, greedy, did not genuinely care about, and lacked the will for resolving these issues. Out of despair, these students suggested that a war would be the solution:

> Interviewer: What if we assume that there has been a really big war. What would happen after the war?
>
> S06: Another war would break out. The developed countries won't be content with it. With their historical exploitative personalities they will want to do the same thing.
>
> S30: If people were actually humans then they might have changed for the better.
>
> S10: But I don't think that is likely (G1).

DISCUSSION

Most of the students considered the SSI dilemmas not as technical but as ethical problems, having their roots in human nature, manifested by the actions of individuals and governments. The students viewed human nature as extremely individualistic and hence must be regulated by a higher authority such as the government. For the students, individuals and governments are not sincere in their efforts related to SSI, leading to doubt; human nature will not change, leading to despair about the possibility of solving the SSI dilemmas. The results expand the cost-benefit analysis explanation for the lack of willingness to take environmental action (Boyes et al, 2009; Chokkar et al., 2011; Kilinc et al., 2011; Rodrigues et al., 2010) and are contrary to that students do not understand the fundamental social impact of undertaking environmental actions (Andersson & Wallin, 2000).

Such a dark point of view from teenagers is alarming. The students do not view themselves as active agents, who can change the state of affairs in the world, hence are not only indifferent about taking pro-environmental action but they consider it as futile. Perceiving that all solution possibilities are in the hands of governments and believing that governments cannot be trusted, they appear to be paralyzed. These results may have cultural explanations, for example, Turkey is becoming a modern democracy but the relative positions of the individual and the state still is quite behind the ideal, which may account for the students' perception of themselves as passive rather than active agents on issues that involve pro-environmental action. Similarly the students may not be trusting to the government because they perceive the government as corrupt. Finally, the students' perception of the Western countries as having great power on international decisions but pursuing only their own benefit may be another explanation.

On the positive side, perhaps not on an individual basis, but the students' collective arguments on the SSI dilemmas seem quite sophisticated. Although the sample consisted of academically talented students, it still is striking that these 16 year olds tackled major philosophical questions about ethics, human nature, individualism versus collectivism, and the problems facing the world. The students lacked scientific knowledge on the SSI dilemmas and there is reason to doubt that they had any philosophical training. Yet, the students were able to capture and argue on these ethical and philosophical issues and their relations to the SSI dilemmas. Previous research (Lewis & Leach, 2006; Ekborg, 2008) already showed that students do not need huge amounts of scientific knowledge to discuss SSI, the current study confirms these results and extend it to philosophical and ethical knowledge; students, in the very least the academically talented, probably do not need huge amounts of philosophical knowledge to engage in SSI discussions. The results also imply that it may be meaningful to focus not solely on epistemology but also on ethics and politics. However, studies with representative samples are required in Turkey and other countries.

NOTES

This study was supported by the Bogazici University Research Fund with project number 1862.

INVESTIGATION OF PRIMARY SCHOOL STUDENTS' ATTITUDES TOWARDS TECHNOLOGY

Gülcan Mıhladız[1], Meltem Duran[2] and M. Zeki Yıldırım[3]
[1]Lect. Dr., Mehmet Akif Ersoy University, Faculty of Education, Primary Education Department, TURKEY
[2]Ph.D. c., Gazi University, Gazi Faculty of Education, Science Education Department, TURKEY
[3]Prof. Dr. Mehmet Akif Ersoy University, Faculty of Education, Science Education Department, TURKEY

Abstract: In this study, it is aimed to determine whether primary school students' attitudes towards technology vary by students' gender, their grades, family income levels and also socio-economic levels of the schools they have studied in. According to the "appropriate sampling" method, 882 students from 6th, 7th and 8th grades in 9 primary schools are included in the study. The Turkish version of Pupils' Attitude towards Technology (PATT-TR) scale which was adapted to Turkish by Yurdugul and Askar (2008) was used in this study. In data analysis, "SPSS 16 Statistical Package Program" was used. According to the results of the study, there was no significant difference between students' attitude scores in terms of their gender. In addition, significant differences were found in students' attitude scores in terms of students' schools, grade levels and their families' income levels. Differences identified in attitude scores of students were found in favor of 6th grade students, the children of middle-level income families, and again students of the schools close to the middle-level socio-economic levels.

Key words: Attitude towards Technology, Primary School, Students, Science and Technology Literacy.

1. INTRODUCTION

One of the most effective elements of the information age, the use of technology does not only make the individual, community and member of a profession more powerful and life-facilitating against events and facts but also imposes new responsibilities the individual, community and member of a profession. It is an undeniable fact that the individual, community and member of a profession who is aware of these responsibilities, who can produce and use technology and who is integrated with technology is always better to be ahead and more powerful (Kısa & Kaya, 2006). In addition, the number of people who state that the use of technology in schools increases student achievement is more than the number of people who say that the use of technology is a waste of time and money (Bransford, Brown & Cocking, 1999). Widespread use of technology at a great pace in the field of education brings the issue of how much technology, due to its positive effects on student achievement, should be included in education programs to the fore. Balcı and Esme (2001) have stated the causes of why technology should be in public education programs respectively; i) education cannot be considered separate from contemporary life and technology, ii) technology increases the creative capacity by developing the critical attitude, iii) technology contributes to the development of intelligence and competence, iv) technology education complements other courses, v) as a result of technology education, no matter when students leave the school, they can be adapted to the technical life they live in. In addition to this, social, political and economic developments in society in parallel with attitudes, needs and values of people are also highly influenced by technology (SSC, 1989). In this context, students' attitudes towards technology and containing technology in science and technology lessons are important.

1.1. Rationale

Since the second half of the 20th century, "understanding of the interaction between science, technology and society" began to gain importance in the field of education. In this context, it is seen that new regulations are brought to science education and scientific literacy to eliminate the problems related to health, natural environment, communication, energy resources, food resources (NRC, 1996). One of the dimensions of scientific literacy, considered as one of the most important goals of modern science education, is an individual's understanding technology and the mutual interaction of technology with science and society (AAAS, 1993; NRC, 1996; Bauer, 1996; Hughes, 1997; Hurd, 1998; Murphy et al., 2001). In this context, it is important to investigate students' attitudes towards technology to let them develop positive attitudes towards technology and understand the nature of science and technology. In this regard, primary school students' attitudes towards technology were investigated in the study in terms of their gender, grade level, family income level and socio-economic levels of schools.

2. METHODOLOGY OF THE STUDY

2.1. Methods

In this study, the survey method was used to investigate the primary school students' attitudes towards technology in terms of demographic variables. The study was performed in the 2009-2010 academic year in the province of Burdur which showed a very high success in high school and university entrance examinations in Turkey.

2.2. Participant

According to the "appropriate sampling" method, 9 of 34 primary schools could be applied an attitude scale. The study sample is consisted of 882 students studying in the 6th, 7th and 8th grades in 9 different primary schools representing lower, middle and upper socio-economic levels.

2.3. Data Collection Tool

"Turkish version of Pupils' Attitude towards Technology (PATT-TR)" scale was used in this study. The scale of Pupils' Attitudes towards Technology (PATT) is a scale developed by Marc de Vries (1988) within the "Students' Attitudes towards Technology" project. In addition, PATT scale is applied in more than 25 countries from the year 2002 (Volk & Ming, 1999) and findings are described in various publications or PATT conferences (cited in Yurdugul & Askar, 2008). Yurdugul and Askar (2008) adapted the PATT scale to Turkish language by carrying out validity and reliability studies. Researchers was found that PATT-TR scale consisting of 24 items have a high item-consistency (ω=.92). The scale is a 5 likert-type scale consisted of four sub-dimensions which are "Tendency to technology", "Negativeness of technology", "Importance of technology" and "Technology for all".

2.4. Data analysis

In order to analyze the data, answers of the students who participated in the study are scored from 1 up to 5 in accordance with 5 Likert-type scale. The total score of attitude towards technology obtained from each student was analyzed using "SPSS 16 Statistical Program". To determine the effect of gender variable on students' attitudes towards technology, “Independent t-test” was used; for the analysis of factors such as grade level, family income and the school’s socio-economic level, the "One Way ANOVA -Post Hoc Tukey HSD" tests were used.

3. RESULTS

In the study, maximum score that students can achieve in the survey of attitudes towards technology is 120 and the minimum score is 24. Students’ mean attitude scores towards technology and other descriptive statistics results have been given in Table 1.

Table 1. *Descriptive statistics results of students’ attitudes towards technology scores*

N	$\overline{X}$	Min.	Max.	SD	Med.	Mod.
882	89,05	39,00	120,00	15,064	90,00	81,00

As can be seen in Table 1., primary school students' scores of the attitudes towards technology was found to be normally distributed. Students obtained a minimum 39 point, and they have obtained a maximum 120 mean attitude point from the scale. In addition, the overall mean score was calculated as 89.05 point. In this context, students’ attitudes towards technology were found to be in positive level. Also, according to likert- type scale, this mean score matches to (3,71 ≅ 4,00; agree) medium level.

Table 2. *Results of the Independent t-test on the mean attitudes scores of students according to gender factor*

Gender	*N*	$\overline{X}$	*SD*	*t*	*p*
Female	436	88,52	14,824	-1,036	,300
Male	446	89,57	15,294		

When students’ attitude scores were evaluated in terms of gender variable, mean attitude score of the female students towards technology was found to be $\overline{x}$=88,52 and that of the male students was found to be $\overline{x}$=89,57. According to analysis, a significant difference was not found between male and female students’ mean scores of attitudes towards technology (p>.05). Also both male and female students have positive and medium level of attitudes towards technology.

Students’ attitudes towards technology were examined in 3 class level and whether students’ attitudes towards technology differ according to grade or not were analyzed by One Way ANOVA test. Results of the students’ attitude scores have been given in Table 3.

Table 3. *Arithmetic Average of the Students' Attitude Scores According to Their Class Levels*

Class Level	N	$\overline{x}$	SD	F	p
6th grade	314	90,64	14,702	3,315	,037
7th grade	295	88,81	14,429		
8th grade	273	87,47	15,992		
Total	882	89,05	15,064		

Considering the mean scores of attitude towards technology of students, it is seen that the students of 6th grade have the highest mean scores of attitude $\overline{x}$ = 90,64 and 8th grade have the lowest mean scores of attitude $\overline{x}$ = 87,47. When the standard deviations are considered, 8th grade students' attitude scores are in a wide range than 6th grade students. It was found that students' attitudes towards technology differ in their class levels (F(2.879)=3.315), p< ,00). Also according to Post-Hoc Tukey analysis a significant difference was found between scores of the 6th and 8th grade students and it was seen that this difference was in favor of the 6th grades.

The names of the schools included in the present study were coded as S1, S2,… S9. The order followed in the coding of the schools is based on the locations and average economic status of the schools. 9 primary school students' attitudes scores of technology were investigated according to their schools' socio economic status. Results of the students' attitude scores according to their schools' socio economic status have been given in Table 4.

Table 4. *Arithmetic Average of the Students' Attitude Scores According to Their Schools*

Primary Schools	N	$\overline{x}$	SD	F	p
S1	106	86,43	15,597	3,439	,001
S2	152	88,02	17,188		
S3	108	90,44	15,284		
S4	113	91,71	12,791		
S5	110	85,78	14,315		
S6	54	94,96	14,242		
S7	101	90,90	13,281		
S8	59	90,27	16,644		
S9	79	86,04	13,180		
Total	882	89,05	15,064		

According to the results of One Way ANOVA, a significant difference was found between students' attitude scores in terms of their school's socio-economic status (F(8.873)=3.439; p<.05). When students' attitude scores are compared with Post Hoc Tukey test according to socio-economic status of schools; a significant difference was found between students whose school's socio-economic level is close to the middle level (S6) and 3 primary schools students whose schools' socio-economic status are very high (S1), medium (S5) and very low (S9). When the eta square value (η^2= .03) is considered, it can be said that the schools' socio economic status variable has small effect on students' attitudes towards technology.

Whether students' attitudes towards technology differ according to their families' income levels or not were examined by using One Way ANOVA test in 4 groups of income levels. The groups of income levels and the results of the analysis have been given in Table 5.

Table 5. *Results of the Students' Attitudes Scores according to Their Families' Income Levels*

Families Income Levels		N	$\overline{x}$	SD	F	p
00TL - 499TL	(a)	168	87,95	15,545		
500TL- 999TL	(b)	245	89,71	14,837		
1.000TL- 1.499TL	(c)	248	91,13	13,887	3,678	,012
1500TL - +++TL	(d)	221	86,81	15,918		
Total		882	89,05	15,064		

As can be seen in Table 5., while the mean income level of the families of the students having the highest attitude scores was found to be between c TL (Turkish Liras), that of the families of the students with the lowest attitude scores was found to be d TL ($\overline{x}$= 74.34). Moreover, according to income level of families, it was found that a significant difference among the students attitude scores (F (3.878)=3.678), p< .05). According the Post Hoc Tukey HSD analysis significant difference was determined between the scores of students which are c TL and d TL income level in c TL favor. This difference was favor of the students of the families with medium income level. When the eta square value (η^2= .012) is considered, it can be said that the families' income level variable has subtle effect on students' attitudes towards technology.

CONCLUSIONS AND IMPLICATIONS

According to our study, there is no differentiation between female and male students' attitudes towards technology. This shows that gender is not a factor affecting attitude towards technology. In parallel, Köse and Gezer (2006) have indicated that there is no difference found between the gender of students and their attitudes towards computer technology. In addition, while some studies (Loyd, Loyd, & Gressard, 1987; Ray, Sormunen & Harris, 1999) talk about females' attitudes being more positive than males', some (Whitley, 1997; Bame & Dugger, 1989) talk about males' having more positive attitudes. In addition, students' attitudes towards technology are affected by students' grade levels. In this regard, the lower levels can be said to be in a more positive attitude than higher levels. In addition, in terms of the income levels of families, attitudes of children towards technology whose families have moderate-level of income are found to be more positive. In parallel, considering the socio-economic levels of schools, students in primary schools whose socio-economic status is in middle level can be said to have more positive attitudes towards technology than schools whose socio-economic status is in other levels.

A FRAMEWORK FOR CONSIDERING CROSS-CULTURAL EXCHANGES AS A WAY TO DEVELOP REASONING ABOUT ENVIRONMENTAL SOCIOSCIENTIFIC ISSUES

Olivier Morin[12], Laurence Simonneaux[2], Russell Tytler[3], Jean Simonneaux[2]
[1]Université Lyon 1 (France)
[2]Ecole nationale de Formation Agronomique, Toulouse Auzeville, UniversitéToulouse 2 (France), UMR
Education Formation Travail Savoirs
[3]Deakin University (Australia)

Abstract: This study analyses the evolution of socioscientific reasoning on sustainability, of French and Australian tertiary students exchanging ideas on a digital platform, concerning local (Australian, French) environmental SSIs, and global environmental SSIs. We explore how the exchange of arguments from various disciplinary and cultural perspectives, can promote reasoning about complex problem-situations in the environment. We develop a framework of reasoning, and show how it enables a productive analysis of the nature of the exchanges, and the quality of reasoning. We argue that such a strategy may improve epistemological training on the nature of science, and citizenship.

Keywords: Socioscientific issues, Reasoning, Sustainability, Cross-cultural, Digital environment

Teaching Socioscientific Issues (SSIs), at a time when scientific expertise is the subject of controversy and debate in society, places risk and uncertainty at the heart of the teaching / learning process. The very nature of SSIs implies argument about them from different domains of reference (in experimental science, humanities and social science) and from social and professional knowledge. We are interested in this study to explore the evolution of students' reasoning about Environmental SSIs (ESSIs), that is to say problem-situations involving tension between the functioning of ecosystems and human interventions related to the management of these ecosystems' products and services.

1. RATIONALE

Awareness of environmental issues in discussions on the appropriate development model for our society is integrated in educational settings linked to sustainable development. Too often, the educational goal is limited to development of good practice (sort waste, carpool ...). We believe that Education for Sustainability (EfS) can also effect change in students' relationship with scientific knowledge, with the assessment of expertise and with the social relations that are involved. EfS thus implies a scientific literacy questioning the relationship between techno-scientific progress and society.

To address ESSIs from different perspectives, through the prism of various and sometime conflicting interests, seems a good way to understand their complex nature. By bringing together students from different scientific disciplines, and from different continents, we explore how the exchange of arguments from various perspectives promotes the perception of complex problem-situations in the environment. We explore how such a strategy may improve epistemological training on the nature of science, and on citizenship.

To reflect the interactive nature of the exchanges, we chose to use categorizations developed by Mercer (1995) from an analysis of linguistic interactions between students. One of the functions of language, according to Vygostski (1985), is to enable learners to organize their own thoughts and give meaning to words. Indeed, Mercer (2002) states that we use language to transform our thinking through individual thought and collective action. Postmodern thought states that any discourse can only be relative because our era has shown that we cannot establish universal standards. With the Theory of Communicative Action (1987) Habermas shows instead that the communicative function can break this deadlock and produce a democratic agreement. Construction of reason passes in effect through intersubjectivity, with communicative action based on mutual understanding, designed for justice more than truth, to coordinate planned actions.

2. METHODS AND RESEARCH QUESTION

We have posed three ESSIs to Australian and French students who were able to meet virtually through a digital platform. We are looking at the possibilities of on-line community interactions contributing to learning and at the aspects of cross cultural interactions which act to broaden students' perspectives on SSIs. The three ESSIs fit into the general theme of "Feeding humanity." We have chosen this theme for its potential to promote individual and collective reflection on the role of expertise in developing a position. Everyone can feel concerned: as a consumer embedded in his social group, as a scientific expert holding more or less current knowledge, or as a "world citizen" involved in a debate on the future.

Our research question is: How do socio-cognitive disturbances, made possible by this cross-cultural approach, contribute to the evolution of socio scientific reasoning in the perspective of sustainability?

2.1 Design of the intervention

The intervention took place during the months of March to June 2011, with thirteen French students from ENFA of Toulouse in their fourth year of a teacher education degree in different disciplines (animal or vegetal production, economy, sociocultural education) and five Australian students which were undertaking their third year of a teacher education degree and specialized in science and environmental education. The two student groups were each divided into three subgroups, each of which took responsibility for discussion and construction of a wiki on one of three socio-scientific sustainability issues. These three issues were designed such that one issue was particularly pertinent to France (4 French & 1 Australian students), one to Australia (4 French & 2 Australian students), and the third was global in nature (5 French & 2 Australian students). The issues involved :

- A green algae outbreak along the coast of Brittany, linked to release of fertilizer by agronomists. The issue thus involved, ostensibly, a conflict of interest between the enjoyment by citizens of the coastal environment, and the needs of the farming community. The issue had a strong 'local' French context but for the Australian students was 'remote'.

- The construction of desalination plants to produce fresh water. This issue was particularly pertinent, and 'local' for the Australian students since following years of drought the Victorian government had commissioned such a plant, against widespread opposition by rural and environmental groups, and taxpayer interests.
- The consumption of meat, which was held to be an issue of global scale, and similar in exposure to the French and Australian students.

The sequence of events was as follows: A media file was prepared for each of the three issues, and uploaded onto the project website. "Forum A" involved discussion separately for the French and Australians. This took place in the groups' first language and led to the construction of a first Wiki by each group, in English. Then the wikis of the French and Australian groups were opened to each other, and a "Forum B" was opened for international exchanges in which each group questioned the other and attempted to come to a common understanding. The last step was the reconstruction of the wikis following this international exchange.

2.2 Analysis framework

Several researchers have developed and modified a grid to analyse socioscientific reasoning (Sadler, Barab & Scott, 2007; Simonneaux & Simonneaux, 2009, Morin & Simonneaux, 2010) to identify the inclusion of uncertainty and complexity in reasoning about problem-situations. The latest version of this grid from the perspective of sustainability (Socioscientific Reasoning and Sustainability: SSR and S) consists of 6 dimensions (Problematization, Scales, Knowledge, Uncertainty, Values, and Regulation). On each dimension 4 levels of depth are defined, through which the level of reasoning can be assessed.

Mercer (1995, 2002) defined three types of discourse: Disputational talk, where the relationship is competitive, differences of opinion are stressed rather than resolved, and the general orientation is defensive. Cumulative talk, where ideas and information are shared rather than discussed in the process of constructing knowledge. Exploratory talk, during which speakers engage in critical but constructive discussion about each other's ideas and alternative viewpoints are suggested. Most studies show by analyzing the language of students during classroom debates that there are mainly disputational and cumulative talks. A number of limitations have been attributed to Mercer's approach, in particular because it doesn't take into account the content of speech. This is why we have added another criterion of analysis, concerning the domain of validity of arguments.

Habermas distinguished between for types of social-interactions according to the domains of validity of arguments in reference to the three dimensions of what he called "real life". We have used this reference to the three worlds to characterize on-line community interactions. In the Objective world, statements or questions are based on logic, empirical efficiency, and scientific truth. In the Social world, interventions enable the speaker to show he is a member of a group by following social norms of behavior, or to question the interactions and regulatory procedures between social actors. In the Subjective world, the speaker expresses his/her personal experiences, his/her affect, his/her own perception of the situation, and considers the views and the subjectivity of his/her interlocutors.

Thus, we have drawn up a tool combining these two theoretical dimensions. According to our research question, the analysis is focused on the differences between the type of contributions before and after the opening of international exchanges.

3. RESULTS

On our design work, we observe a lot of cumulative talks, in which reasoning was supposed pre-existing and individual positions already determined. Two other types of talk have been observed. In both, the participant's position is not predetermined: i) in the third type, participation is directed towards the development of individual reasoning, just as in the exploratory talk of Mercer, ii) in the last type, that we have called " Inte gr ati ve talk ",
participation aims at integrating new features into the collective reasoning.

	Cumulative talk	**Exploratory talk**	**Integrative talk**
Reference to the objective world	EXPOSURE The response is affirmative and is based on logic, empirical efficiency, scientific truth. Knowledge is presented as certain. Rationality is technical, instrumental.	REFLECTION The contributions point to differences in statements, doubts, judgments on consistency with the positions of the speaker. The search for new knowledge may be considered.	DISCUSSION Participation is an exploration of the conditions of validity of knowledge on which controversies may be resolved. Rationality is critical.
Reference to the social world	IDENTIFICATION The procedure allows the speaker to show membership in a group. The statements are based on the values of this social group.	RECOGNITION The contribution considers the views of other participants or the views of several categories of social actors. The speaker can ask questions of other participants.	CONFRONTATION Participation is a weighing of different expressions of the interests of stakeholders. The speaker discusses social choices, and regulatory procedures between the categories of social actors.
Reference to the subjective world	TESTIMONY The response expresses the opinion of the speaker, which refers to personal experience. He expresses his emotion, his own perception of risk, or the values underlying personal commitment.	ASSESSMENT The contribution considers views different from those of the speaker, which identifies the values taken by others. The speaker can make judgments, but changes of opinion are possible.	DELIBERATION Participation considers what may be conflicts of values and discusses the principles at stake. The differences are acknowledged and can allow the emergence of new judgment criteria.

Table 1 : Analysis framework

3.1 Impact of contextualizing ESSIs

With the **GREEN ALGAE issue**, it seems that the significance of individual experience is decisive. The introduction of the French wiki gives a sense of the tone: "*I remember swimming and fishing near the river, this was a very important place where every child went after school. I remember when on Sundays we went with my family to the sea smelling the good air and seeing the beautiful landscape. It was few years ago... "*. It is possible for personal commitments to overshadow a more dispassionate consideration of the different interests at stake and the wider social policy ramifications. During the exchanges about this issue, the participations often remained as testimony. Table 2 gives the analysis of these first phase exchanges:

	Cumulative	Exploratory	Integrating
Objective	4	1	1
Social	1	3	
Subjective	4	2	

Table 2: Green algae, French discussions in the first phase, March 14 to May 19 (16 entries)

In the second phase, we collected only a few international exchanges. Most of the discussions are of the cumulative type:

	Cumulative	Exploratory	Integrating
Objective	1		
Social	2	1	
Subjective	4	1	

Table 3: Green algae, international exchanges, May 29 to June 15 (9 entries)

With the **SEAWATER DESALINATION issue**, one can compare the contributions of the 'local' and 'remote' participants. It seemed that little is known by the "remote" participants and this naturally leads to a search for objective information (9 out of 10 exchanges in the first phase of treatment came from French participants):

	Cumulative	Exploratory	Integrating
Objective	10	3	1
Social			2
Subjective		5	1

Table 4: Seawater desalination, discussions in the first phase, Mars 14 to May 15 (22 entries)

The first French wiki talked about the problem with a reserved attitude. They took the position of distanced commentators and their group did not feel compelled to commit to a position. They did not enter into the topics proposed for the wiki and only one of the four participants gave the only contribution to finding a possible action. They considered the issues on a global scale but did not engage with local contextual interests and alternative approaches. On the other hand, the Australian students positioned themselves as activists in their consideration of the issues. Their wiki was much more focused on social and technical aspects of local controversy. While one of the two participants reported extensively on the views of stakeholders, the other listed possible solutions implemented locally such as the use of "rainwater tanks". This situated approach seems to have led them to tackle more political issues.

3.2 International interaction and growth in understanding of other perspectives

To what extent did our design work engage students in genuine debate? The discussion about the desalination issue of the first phase was very cumulative, then became exploratory in the second phase during Franco-Australian exchanges (period from May the fifteenth to June the seventeenth). Each highlighted aspects of the controversy he or she considered important, and brought them to the debate. For instance: (French student) *" You* *bring a substitute solution which we French students had not thought about "Using rainwater tanks on all houses to supply water". This idea does not seem to me to answer the need for water in Australia. […]. Rainwater tanks are ineffective in this use."*(Answer of an Australian student) *"I too agree that rainwater tanks are not the solution. However, in saying that, they can be a great way to save a lot of water. My family live in country Victoria […]and are completely self sufficient in their water use through installing two large rainwater tanks. […] Therefore, I believe by most houses being able to supply even a small portion of their daily water use from rainwater tanks, it can help alleviate the water shortage we have here."*

The complexity of the controversy is explored further in that second phase, especially in the second column (13 entries out of 27) that identifies the stakes for participants:

	Cumulative	Exploratory	Integrating
Objective	4	5	2
Social		4	1
Subjective	4	4	3

Table 5: Seawater desalination, international exchanges, May 15 to June 17 (27 entries)

The attitude of the international group became proactive and each participant through investigation built their critical thinking. It seems here that international exchanges have contributed to more than the juxtaposition of elements. They have led everyone to be clearer with his or her own position.

The **MEAT CONSUMPTION issue** is also one in which personal context is very apparent. Very quickly in the forum, exchanges moved to declaration of each individual's consumption of meat which placed the problem in a personal context and displayed identity commitments: *"I come from the southwest, a part of France where food is very important. At my grandmother's for dinner …."* "*We Aussies like our barbies"…* Different aspects of the debate were opened up, as different positions were dealt with: "*Looking at it from an individual perspective, I believe that it would be impossible logistically to outright stop meat production. Too much is reliant on its continuation (people's livelihoods, demand within the market, obvious health benefits etc)".*

But the construction of the wiki tended to be organized around a division of labor (no action on the French wiki involved the removal or modification of what others had written), with a propensity to neutralize the discussion.

	Cumulative	Exploratory	Integrating
Objective	14	8	2
Social	2	3	1
Subjective	6	4	1

Table 6: Meat consumption, discussions in the first phase, Mars 12 to May 15 (41 entries)

Note that in the first phase, entries are mainly references to the objective world (first row, 24 of 41) and result in a juxtaposition of individual claims (first column 22 of 41). The attitude of the group is retroactive, the communication mode is the "strategic action" of Habermas and the activity is considered as a presentation. The partners are building a common knowledge accumulation, but the decision for action is vested in the reader.

In contrast, the second phase of exchanges is distributed more evenly between the three lines, and three columns.

	Cumulative	Exploratory	Integrating
Objective	4	2	3
Social	5	7	1
Subjective	3	8	6

Table 7: Meat consumption, international exchanges, May 15 to June 20 (39 entries)

As with the desalination issue, the activity of the group became proactive and generated more "communicative action", referring to the three "worlds" of Habermas. The discussion became more exploratory. The wiki was seen as a rational presentation of views, which may be different.

Conclusion

The interactional socio-scientific reasoning framework proved fruitful for analysing these online community interactions, in particular because it opened up new ways of looking at these exchanges and it helped to understand that reasoning collectively at a high level require arguments across the three worlds in integrative exchanges. We can argue that features of the digital environment both support and constrain students' reasoning on SSIs, with a lack of dispute in forums and wikis, and the problem of distribution of responsibility on the one hand, and with the value of the international forum in creating the requisite disturbance on the positive side. We conclude that cross cultural exchanges add to the richness of student reasoning both through local vs remote perspectives, and different cultural standpoints. Our team is now developing a new research aiming at a better balance between face to face and online position development. We propose a hybrid system in which students will debate in class, in groups, prior to the use of the digital platform to develop the wiki. We will maintain a commitment to an international forum in which the wiki of each group is opened to scrutiny by the other.

MORAL DEVELOPMENT IN SCHOOL SCIENCE TEACHING: EXPLORING AN INTERFACE OF CONTRIBUTIONS

Roberto Nardi[1] *and Julio César Castilho Razera*[2]
[1] Universidade Estadual Paulista "Júlio de Mesquita Filho", UNESP, São Paulo, Brasil
[2] Universidade Estadual do Sudoeste da Bahia, UESB, Bahia, Brasil

Abstract: In the field of Science Education there are many arguments in order to take more attention to the axiological and attitudinal dimensions of the teaching and learning scientific disciplines processes. This demand requires continuous in-depth investigation about this theme because it involves the knowledge of various theoretical fields that have not still attracted the deserved attention. In the light of developmental psychology and discursive ethics, the present study focuses on a relevant component of the attitudinal-axiological dimension: the moral development of students in Science classes. Based on the sociomoral perspectives in Piaget, Kohlberg and Habermas theories, we have attempted to answer the following question: What correlation can we establish between the moral development of students and school science teaching? Following this point of view and the respective problem, we present outcomes of a study containing arguments that explore a valid and viable correlation of secular and rational theoretical and practical aspects and components between school science teaching and moral development, including an analysis of the knowledge about moral, critical and scientific thinking of students learning science. Our study demonstrates the existence of an interface of reciprocal and plausible theoretical and practical contributions between moral development and school science teaching, which has so far received little attention in the Science Education research.

Keywords: science teaching; moral thinking; socio-scientific issues; Kohlberg; Piaget.

DEVELOPMENT MORAL: AN ATTITUDINAL-AXIOLOGICAL DIMENSION IN SCIENCE EDUCATION

The epistemic factors have received increased attention in Science Education research. However, non-epistemic factors (moral, affection, political etc.) have so far been little explored. We understand that more consideration should be given to these non-epistemic factors since they also integrate the lines of reasoning and arguments in the decision making process for addressing technical and scientific issues (Acevedo, 2006). Solbes (2009) presents another line of discussion, though with similar concerns. The author affirms that the difficulties encountered by students in learning Science are not restricted to conceptual deficiencies because the process of conceptual learning is aligned to several other aspects like reasoning strategies, affective relationships, classroom atmosphere and motivations. These aspects can be either, favourable or unfavourable to the teaching and learning of science; in this case, the procedural and axiological dimensions are also necessary in conceptual learning.

In the Science Education research literature we have found other arguments that support the need for attention to the axiological and attitudinal dimensions in the science teaching (Zeidler, 2003; Lemke, 2006; Sadler et al., 2006; Reis, 2007). Nevertheless, we found few studies about this subject, which should deserve more attention due to the relevance and complexity of the theme, which involves other knowledge fields such as philosophy and psychology.

In the light of developmental psychology and discursive ethics, the present study focuses on a relevant component of the attitudinal-axiological dimension: the moral development of students in science classes. Based on the sociomoral perspectives in Piaget, Kohlberg and Habermas theories, we have attempted to answer the following question: What correlation can be established between the moral development of students and school science teaching? Our study was focused on moral development because the theoretical foundations of this process may help us understand students' moral reasoning and creative thinking construction. According to Simmons and Zeidler (2003), there is an interaction between these two constructions that should be better explored in science education. Our study attempts to help exploring these possible contributions.

Following this outlook, and based on the above mentioned problem, the present theoretical study explores correlated aspects (of principles, contents, procedures, etc.) between moral development and school science teaching. Within the scope of this synopsis, we briefly present: i) a set of ideas and principles of education, science education and sociomoral perspectives according to Piaget, Kohlberg and Habermas; ii) a delineation of arguments, exercises and analyses that contemplates a juxtaposition of aspects and components under the sociomoral perspectives and the axiological needs about the science teaching, configuring a delineation of potential correlations between school science teaching and students' moral development.

SCHOOL SCIENCE TEACHING AND SOCIOMORAL PERSPECTIVES: THEORICAL APPROACHES

Some of the identified principles and ideas in Education, Science Education and sociomoral perspectives that we followed are: i) Education implies in moral formation; ii) school education plays a relevant role in the "search for the truth"; iii) The science curriculum should include ethical and moral issues, implying in theoretical and practical needs to support these discussions; iv) Science and science teaching present ethical and moral aspects at different plans and logical levels; v) Science versus religion, idea and search for the truth, common sense, nature of science, scientific practice, controversial socio-scientific topics and discourses / languages on science are components presented in science classes that have the potential to generate in students critical thinking and intellectual and moral independence; vi) According to Piaget, the morality is not innate, but also acquired by learning; vii) Piaget (1992) reports two stages of moral: *heteronomy* – obedience motivated by either, external or self-centred control (e.g. fear of punishment) - and *autonomy* – obedience motivated by internal consciousness; viii) Imposition, coercion and unilateralism are elements that do not lead to autonomy, because they reinforce heteronomy; on the other hand, cooperation, dialogue and mutual agreement are key elements for developing moral autonomy (Piaget, 1992); ix) Kohlberg (1992) indicates three levels of moral development: *Pre-Conventional* – guided by obedience, punishment, selfish-naïve of submission to a higher force; *Conventional* – centred on conformity to the conventional order and on meeting other people's expectations; *Post-Conventional* – characterized by the distinction of valid values and principles regardless of the authority; x) The ethical discourse is a form of communication aimed to justify the claims of validity of opinions and interaction norms. By means of the language, a consensus completely free from external and internal coercion is sought. We may assume that something is good or real by using force or imposition (heteronomy) or by establishing a dialogue (autonomy) where other people's arguments may change someone's opinion. In the first case, there is a supposed authoritative power (heteronomy); in the second case, a validity claim. When the supposed authoritative power prevails, the argument of force is applied (unfavourable to moral development). When people are open to validity claims, they are guided by the force of arguments – which favours moral development (Habermas, 2008); xi) Piaget, Kohlberg and Habermas theories are based on rationalism, cognitivism, constructivism and moral principles of justice, cooperation, equity and truth.

DELINEATING CORRELATIONS BETWEEN MORAL DEVELOPMENT AND SCHOOL SCIENCE TEACHING

Various theoretical and practical aspects and components extracted from education, science education and sociomoral perspectives can help us to organize two "moral atmospheres" – concepts adapted from Kohlberg (Table 1). Each one of them combines elements that may, by means of correlation, reinforce moral heteronomy and cause damage to the teaching of Science, or guide the search for moral autonomy and to favour science learning.

Table 1 Two "moral atmospheres"

Atmosphere of moral autonomy and for favouring science learning (some examples)	Atmosphere of moral heteronomy and damage to science learning (some examples)
• Obedience motivated by internal control.	• Obedience motivated by external control.
• Does not impose an a priori truth to the child; the child is not compelled to accept such truth.	• Imposes an a priori truth to the child, who is compelled to accept it.
• Centred in post-conventional level.	• Centred in pre-conventional level.
• Use of discursive arguments with validity claims.	• Use of discursive arguments, with a supposed authoritative power.
• Prevalence of Habermas' theory of communicative action.	• Prevalence of instrumental action.
• An idea of provisional truth and science as a process.	• An idea of absolute truth and science as a finished product.
• Science is not considered a monolithic authority.	• Science considered as a monolithic authority.
• Critical and non-relativist understanding of the different types of knowledge.	• Uncritical and relativist understanding of the different types of knowledge.
• Non-scientific knowledge brought by students that are not previously rejected, nor contemptuously ignored.	• Non-scientific knowledge brought by students previously rejected or contemptuously ignored.
• Demonstration of real interest in the subject while "talking about science".	• No real interest demonstrated in "talking about science".
• Mobilization for students' critical stance towards different types of "evidence" (favouring a critical stance of students towards their initial beliefs).	• "Lack of mobilization regarding the "blind faith" of students on "their evidence" (persistence of an uncritical stance).
•Understanding that surpasses an internalist view of science.	• Understanding that does not go beyond the internalist view of science.
• Ideas, principles, procedures and contents that favour an accessible science.	• Ideas, principles, procedures and contents that favour an inaccessible science.
• Scientific knowledge is not used as an instrument of oppression, coercion or constraint.	• Use of scientific knowledge as an instrument of oppression, coercion or constraint.

We used these approaches in various exercises in real and hypothetic situations to support our arguments for delineating correlate contributions between school science teaching and moral development. Table 2 includes some of these analyzed exercises.

Table 2 Analyzed exercise

Enunciation: *Researchers of the University of California found in the United States Department of Defense a document that classifies homosexuality as a "mental disorder"* (Science Teacher - Partially simulated situation).	
Hypotheses	**Moral atmosphere (implications for moral evolution and learning of Science)**
Science teacher in a reduced and merely informative discourse without proposing a debate or critical stance towards the event.	Reinforcement of moral heteronomy and damage to the teaching of Science: Idea of absolute truth and science as a finished product; strategies that stimulate students' moral reasoning of the students are not used; controversial themes to be discussed in classroom are not included, or there is poor use of such themes, which does not mobilize critical thinking and the development of autonomy; truth is not a value to be sought; understanding does not go beyond the internalist view of science, etc.
Use of discourse as a strategy of debate by the Science teacher.	Search for moral autonomy and in favour of the learning of Science: Idea of a provisional truth and science as a process; use of strategies that benefit heterogeneity and diversity in science classes, aiming at promoting students' moral reasoning development; use of controversies, by means of dilemmas and their respective moral reasoning; truth as the value to be sought; understanding that goes beyond the internalist view of science, etc.

SOME OUTCOMES

This study shows that we were able to confirm the existence of an interface of valid, plausible and viable correlated contributions between the aspects and components of the secular and rational theoretical and practical foundations of moral development and school science teaching – an interfacial correlation that needs further investigation. The possibilities of contribution identified represent a two-way process, that is, as science teaching potentiates the moral development in students, it also enhances science teaching and learning and vice-versa (as science teaching and learning is potentiated, through the several presuppositions underlying the axiological needs, students' moral development and critical autonomy is also potentiated). In short, there is a very important relationship between the two processes, as showed below (Figure 1).

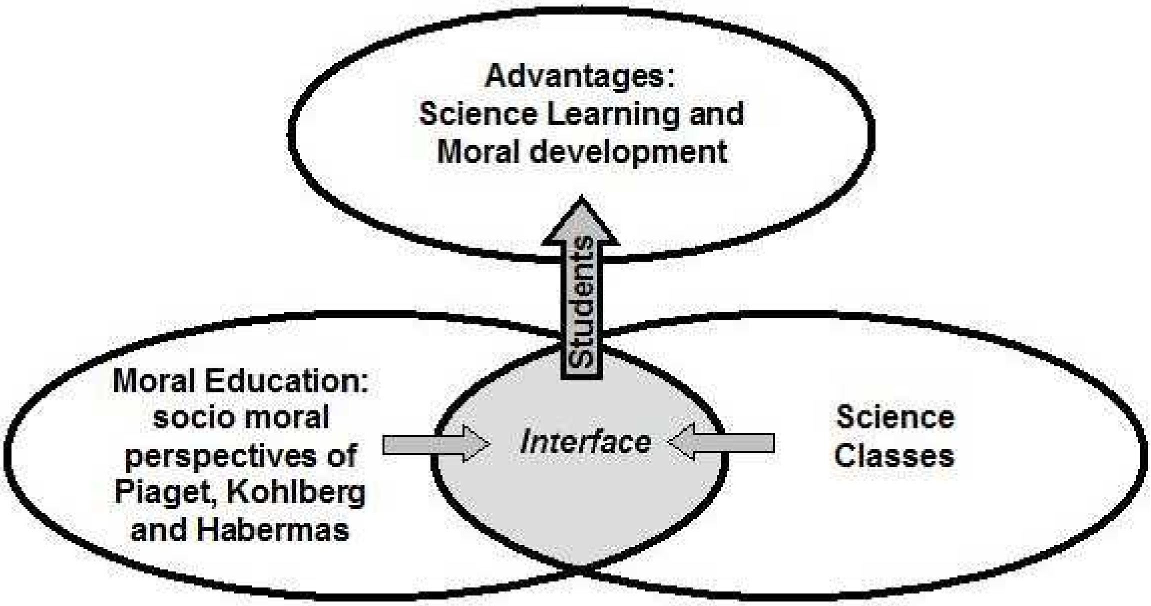

Fig. 1 Interface of contributions

CRITICAL READIND ACTIVITIES TO DEVELOP CRITICAL THINKING IN SCIENCE CLASSES

Begoña Oliveras[1]; Conxita Márquez[2] and Neus Sanmartí[3]
[1, 2, 3] Department of Science and Mathematics Education, University Autonoma of Barcelona, Bellaterra, Barcelona, Spain

Abstract: The aim of this research is to identify the difficulties experienced by secondary school students (aged 15 to 16) with the critical reading of newspaper articles with scientific content. Two newspaper critical reading activities in relation to the study of various scientific contents were designed and carried out in two schools (61 students in total), one with a student population from a medium to high social and economic bracket (school 2) and the other with students from a medium to low social and economic bracket (school 1), and both with different teaching methods. In school 1, the students usually worked in cooperative groups and discussion and self-regulation by students were encouraged. The methodology could be considered to be "student-centred-oriented" according to the classification devised by Kember (1997). In school 2 particular emphasis was placed on reading comprehension and on writing abilities across all areas but, on the other hand, the students never worked in cooperative groups. The teaching was based on the transfer of information by the teacher and the methodology could be considered to "teacher-centred-oriented". The two schools were characterised by the importance placed on experimental work. In order to analyse the difficulties "Elements of Science Critical Reading" were identified on the basis of the "Elements of Reasoning" of Paul & Elder (2006) and the categories proposed by Bartz (2002) in his C.R.I.T.I.C. questionnaire and a scale was drawn up.

Keywords: Critical thinking, literacy, high schools, abilities and critical reading.

INTRODUCTION

Background and rationale

Reading is a fundamental process in science learning since it is not only one of the most often used resources during the school years but can also become a basic tool for ongoing learning throughout life. The media and particularly the written press provide the main sources of scientific information for most adults (Jarman & McClune, 2002). In these media, opinions and actions are often based on scientific knowledge which the reader needs to know how to analyse critically.

Reading means understanding, interpreting, analysing and criticising texts. This is the basic meaning of literacy (Norris & Phillips, 2003). Critical reading and, therefore critical thinking, depend on the context and culture in which they are situated (Yore, Craig & Maguire, 1998). In this research we have focused on assessing critical thinking abilities based on the proposal by Paul and Elder (2005) and Bartz (2002) in the form of the C.R.I.T.I.C acronym. Based on these two approaches, we identified certain "Elements of science critical reading" that we considered useful to guide the critical reading of newspaper articles with scientific content and also to analyse students' difficulties (see Table 1).

Objectives of the research

The specific objectives of the research are as follows:

1) To analyse students' difficulties in applying the "Elements of science critical Reading" defined in the reading of press articles.
2) Identify in relation to which "Elements of science critical Reading" differences are detected in the two samples analysed (school 1 and school 2).
3) Identify how the content of the readings and the types of questions raised in the activities affect the students' answers.

METHODOLOGY

Project description

The first phase of the research consisted of selecting two newspaper texts with scientific content. The subject of the first article was the difficulty involved in removing graffiti on glass. According to the author of the new report, graffiti on glass is so difficult to remove because graffiti writers mix acid with the paints they use. This article was chosen so that the students could apply their knowledge of chemical change. Since the information in the text was not completely correct, because acids (apart from hydrofluoric acid) do not react with glass, the students were able to question the scientific basis of the news story. The second article contained opinions for and against whether the swimsuits used by swimmers had helped improve the latest Olympic records. In this case the article was chosen so that the students could apply their knowledge of cynematics and dynamics to the analysis of an actual event.To encourage critical reading of the articles and reflection, two critical reading activities were proposed (activity 1_ Grafittis and activity 2_ Swimsuits) which included questions relating to those shown in Table 1. There were other methodological strategies related to cooperational learning and group discussion (Márquez & Prat, 2005; Oliveras, Márquez & Sanmartí, 2011).

"Elements of Science Critical Reading"	Examples of question types posed in classroom activities
1. Identify the main ideas of the text	-What problem does the text present? What is the main idea?
2. Identify the writer's purpose	-Who wrote this document?-Why must he or she have written it?
3. Identify the writer's assumptions and viewpoints	- What assumptions does the writer make in the text? Are they justifiable?
4. Formulate a scientific question which the writer answers in the article or design a scientific experiment to verify the information in the text	-Could an experiment or test be carried out to verify the credibility of the main assumption? What question would a scientist ask to investigate this problem?
5. Identify data and evidence given in the text	-Are there any arguments or scientific evidence in the text that support the initial assumption? Write them down.
6. Draw conclusions based on the evidence	-Are the conclusions in line with the current scientific knowledge you have?

Table 1. "Elements of science critical reading

Research population

The research was conducted in two secondary schools in Catalonia (Spain). School 1 is situated in Barcelona and its students come from a low social and economic bracket, with 30% of them being immigrants. School 2 is in a town, near Barcelona with a population of 4,000 and its students are from a medium to high social and cultural bracket, with 9% being immigrants. A total of 61 students took part (15 to 16 years of age), 30 in school 1 and 31 in school 2.

Data analysis

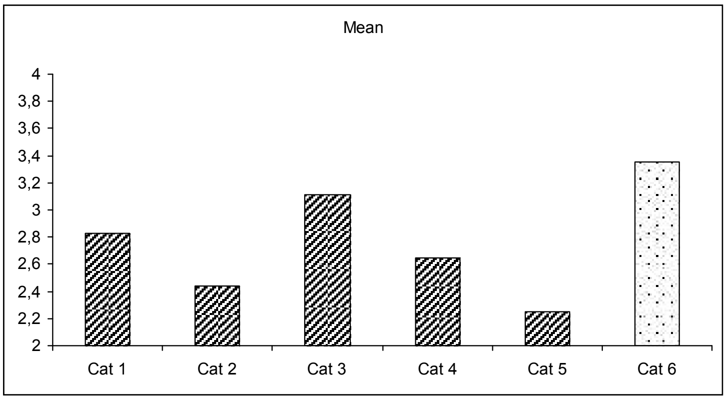
Based on the "Elements of critical reading" we defined six categories used to analyse the data collected in this study. Depending on the students' answers, a scale of 1 to 5 was devised. The scale and the classification of the students' answers were validated by two experienced teachers.
The average scores in each category between the two schools and the two activities were compared, together with the interaction between them, using a two-way analysis of variance (ANOVA). All statistical tests were assessed as significant when the p values obtained were less than 0.05.

Codes	Categories
C1	Identification of the main ideas of the text
C2	Identification of the writer's purpose
C3	Identification of the writer's assumptions and viewpoints
C4	Formulation of a scientific question which the writer answers (article 1) or Design of a scientific experiment to verify the information in the text (article 2)
C5	Identification of data and evidence given in the text
C6	Arguing conclusions based on evidence

Table 2: "Codes and Categories"

RESULTS AND DISCUSSION

To achieve objective 1 of the research we focused on the means in each category. The results (see Figure 1) show that category 2 (identify the writer's purpose) and category 5 (identify data and evidence given in the text) were those that students found the most difficult overall.



"Fig1. Average scores in each category"

In relation to category 2 the results can be explained by the fact that most of the students were convinced that the purpose of the text was to inform and that this information is always neutral and unbiased. Very few students detected that there could be a particular intention in their written work.

With respect to category 5, the difficulties detected related to the assumption by the students that a journalist is an informed and qualified person. If, in addition, the text contained a word that they considered to be scientific (acid, floatability, concentration, etc.), they considered this to be a sufficient indicator to support the scientific basis of the news story and, therefore, they saw it as proof of what the writer said.

To achieve objective 2 of the research we compared the results of the two schools according to the various categories. The results in Table 3 show that there was a significant difference between them with respect to categories 1, 4 and 6.

	School 1	**School 2**	**p**
C1	2.23±1.0	3.43±1.2	<0.01
C2	2.20±1.0	2.69±1.2	0.184
C3	2.78±1.3	3.41±1.3	0.069
C4	2.31±1.0	3.00±1.4	<0.05
C5	2.30±1.2	2.21±1.0	0.128
C6	4.26±1.1	2.44±.5	<0.001

"Table 3. Means plus standard deviation (mean± SD) for each school (N=61)"

Table 3 shows that the results in categories 1 and 4 were better in school 2 in the two activities whereas the results in category 6 were better in school 1 in the two activities. To explain the results we took into account the differences in the teaching methods used at the two schools.

In relation to objective 3 of the research the results of the activities carried out were compared according to the various categories (Table 4).

	Activity 1 (Graffiti)	Activity 2 (Speedo)	p
Cat 1	2.88±1.4	2.81±1.2	0.821
Cat 2	2.60±1.2	2.31±1.1	0.251
Cat 3	2.91±1.5	3.24±1.2	0.323
Cat 4	2.10±0.6	3.11±1.4	<0.05
Cat 5	1.30±0.7	3.04±0.7	<0.001
Cat 6	3.50±1.6	3.25±1.7	0.804

Table 4.Means plus standard deviation (mean± SD) for each activity (N=61)"

The results show that there are significant differences in categories 4 and 5, but not in the rest. As for category 4, activity 1 (graffiti) required the students to formulate a problem that could be scientifically investigated, without the text giving any clues. In contrast, in activity 2 (swimsuits) the problem was presented and the students were asked to think of a scientific experiment to prove whether or not the swimsuits contributed to improving swimmers' speed. As could be expected, the results showed that the students found it more difficult to think of problems that could be scientifically investigated than scientific experiments that could be performed to answer a question.

Category 5 was also very different in the two activities. It was shown that the information provided in the text had an influence on recognising the evidence. If the texts contained information with a scientific basis, the students who understood the scientific model then recognised it. On the other hand, students invented evidence or made unfounded assumptions since, initially, they were completely confident that the writer's statements were true.

CONCLUSIONS AND IMPLICATIONS

The students' answers show that it is not easy to apply critical thinking to the analysis of texts. We identified that there are aspects of critical thinking where students have greater difficulties: identifying the writer's purpose (C2) and looking for evidence in a text (C5) (Figure 1). Significant differences were detected between the two schools (Table 3). The students at school 2 showed greater reading comprehension abilities and written expression (C1) but, on the other hand, they had more problems with the critical analysis of the texts (C6). We can assume that the social and cultural level of these school's students helps them achieve better reading comprehension and writing skills. As for the problems with critical analysis of the information, we believe that these could be due to the different teaching methods used in science classes in the two schools (Kember, 1997). In school 1, the students work on science in a more reflective way, interaction between students and between the students and teachers is encouraged.

In this study we put forward a proposal for working critically with newspaper articles but we think that without a belief in the importance of class discussion (Paul, 1992) on the interpretation of facts with a scientific basis it is difficult for students to develop critical thinking. Authors such as Osborne (2010) and Hayes & Devitt (2008) take the view that collaborative discourse between students represents the ideal means to help students improve the quality of their thinking, always taking into account that discussions need to be regulated and guided by the teacher.

We also detected significant differences in some categories depending on the activities involved (Table 4). Specifically in category 4 and in category 5. In relation to category 4, the students had more difficulties formulating a scientific question relating to a subject than in designing a scientific experiment to verify specific information in the text. As for category 5, if the text does not contain scientific arguments, data or evidence to support the information, the students make unfounded assumptions and consider them as such, since they are convinced that information always has a basis.
We can conclude that the critical reading activities analysed helped to connect different concepts studied in science classes and apply them to the analysis of a real-life problem. After carrying out the activities, the students asked to do more of them which means we can say that they encouraged an interest in reading current texts and analysing them critically, besides applying the scientific knowledge they had learnt. This suggests that students find this type of activity motivating (Nolen, 2003).
Lastly, it is important to state that the objectives associated with critical reading cannot be achieved in a single activity and, therefore, they must be included regularly throughout the students' school career.

TALKING SCIENCE: THE POPULAR ASTRONOMY OF CAMILLE FLAMMARION [1]

Silvania Sousa do Nascimento[1]
[1]FAE/UFMG/Brazil

Abstract: In scientific practice, there is no image by image. The image is still regarded as a process, the result of a theory or reasoning or a model representation. This article will introduce the discussion on the functioning of images in a popularization science work. We analyze the fifth edition the “Astronomy Popular” of Camille Flammarion. In this study we have taken the discourse functioning concepts proposed by Michel Foucault to analyze one semiotic system. In conclusion the study indicates a functioning of illustration and a demonstration of the evidence "do science" in this work.

Keywords: Camille Flammarion, the popularization of science, the discourse functioning, popular astronomy.

INTRODUCTION

Image in science is an association among a technical process, a referent, a phenomenon or an object that one wants to observe or represent, as well as a scientific model. Without these associations, an image in science is just a visual element, a characteristic which marks the memory. It may be a summary of an equation, a mathematical or physical concept or even the creation of lines and colors of a mathematical model. According to Sicard (1997), these images have two iconic paradigms: the first, similar to photographic, a tool captures a fraction of real object, while the second captures a diagram of operation, punctuates what must be seen. The images in scientific research apparently belong to the second paradigm, nonetheless the science popularization should be working more with the first one. It is this assumption which directs our work to investigate the functioning of the images included in a science popularization text.

The images in sciences to Latour (1997) are often "technical images", the result of an "regard orchestrated" by artifacts or theories. The image capture, however, is not enough for science. Robert Hooke and Antonie van Leeuwenhoek, through the microscope which was built in the seventeenth century, observed the plant cells. Only a century later, the cell theory could give a meaning to this observation.

Astronomy has a pioneering role in the development of images in sciences. The introduction of the telescope, according to Bennett (2007), has transformed the instruments of astronomical observation in the seventeenth-century. Until 1609, before the construction of the astronomical telescope of Galilee, astronomers with only the power of their eyes and looking at a small fraction of the electromagnetic spectrum started the adventure of sciences with the image in meticulous drawings which were the instruments of their arguments.

The images produced by science have become more and more complex in the extent that technology has the interaction with possible differentiated levels of energy in production. The new instruments: an electron microscope, a positron camera or a system of satellite-tracking, on the other hand, have lost the dialog with the human dimension. In this context, I will discuss, in seeking to query its pragmatic functioning within science popularization discourse, all contained in the 1955 Nicolas Camille Flammarion fifth edition of "Popular Astronomy”.

THE IMAGE IN DIALOG WITH A TEXT

When we talk about images inserted in sciences text, two natures emerge. The first nature of the image is the reflection on a mirrored surface, and the second nature of the illustration is the representation pictorial, which indicates what seems to be seen. I will consider Michel Foucault’s definition (2000) of discursive procedures group which coordinates the discourse order. Such works differentiate the penetration of subjects in the discourse products. The image is an important element in all languages: natural, mathematics, iconic, graphics among other things and, it may be considered a component of a communicational act where social actors build and share a universe of meaning.

To consume the communication act, the interlocutors are legitimate as communicating subjects who share intentions, purposes, intersubjectivites and ways of expression adjusted to the communicative situation (Nascimento, 2007).

In the study that we propose in this article, we analyze a general public book, which we can characterize as a science popularization work. The studies on science popularization texts, developed by Daniel Jacobi (1998), indicate a dynamic of writing around the concepts and the scientific terms which are employed for the circulation of scientific knowledge outside from their production and validation sphere.

THE POPULAR ASTRONOMY OF CAMILLE FLAMMARION

For Carle and Guédon (1988), science popularization, non-formal or informal education composed by a nomenclature, is still subject of controversy, but these authors suppose that we are talking about the promotion of public access to knowledge and to scientific and technological information by means of mechanisms of differentiated schooling. The astronomer Nicolas Camille Flammarion (1842-1924) has devoted his life to the disclosure of astronomical research. Its main publication, "Popular Astronomy", was published in 1879. His work includes books, directories and journal articles and, in 1882, he founded the Popular Astronomy magazine, a monthly bulletin which were broadly disseminated.

For Jeanneret (1994), Flammarion participates in a "extension program" committed "to say the reality" by proposing moving away from a theoretical discourse which characterizes the scientific language. Popular Astronomy presents very rich and some colored pages and it is a continuous text, cut by chapters with attractive titles, for example, the Earth in the sky. Eventually, the title is accompanied by a brief indication of the covered subjects: how Earth turns on itself and around the Sun... Each illustration has a title, which sometimes, is reported in the text. Before it, there is a text to read in its entirety, similar to other texts about the disclosure of time (JEANNERET, 1994: 256).

In all the six books, as well as on the astronomy´s instruments annex directed to amateurs astronomers, we find 819 images numbered, two celestial charts, tables with astronomical data and an index. Most of these images (607 out of 819) are photographs with illustrative function surrounded by Jacobi´s framework. There are also celestial and land charts (28), systems of graphs (155 tables, graphs and diagrams) and schemes (29). The presentation of each book is almost always preceded by a colorful image, being all the other photographs in black and white. The intention of the popularization without trivializing science is reached from restatements of scientific discourse considering the first discourse. The science popularization discourse, with the restatements which are characteristics, is well marked, for example, by the complete explanation of elements which make up the project.

> Camille Flammarion aimait dire qu'il faut vulgariser la science sans la rendre vulgaire. Telle est la formule qu'il a appliquée dans cette Astronomie Populaire, dont le succès immense a contribué à répandre les connaissances astronomiques et a suscité de nombreuses vocation d'astronomes.Mais cet ouvrage irremplaçable exigeait aujourd'hui une refonte complète: sans en altérer le plan, il convenait d'y introduire les étonnates découvertes de la science contemporaine, et notamment un tableau de l'univers sidéral d'une telle ampleur que l'imagination bardie de Flammarion lui-même n'arait jamais osé le concevoir. Heureusement, l'éducation scientifique du public actuel l'a préparé à recevoir l'enseignement direct des faits et à goûter la poésie des spectacles grandioses qu'un abondante illustration photographique met ici sous ses yeux. (1955:p.3 griffin our)

In this book, the discourse, in general, is restated by the explanation in different languages, for example, the photography below 351 (p.249) which illustrates the nuclear reactions represents a descriptive form (1 Carbone^{12} + Proton = Azote^{13} + Energy) and an explanatory text.

IMPLICATIONS FOR THE SCIENCE POPULARIZATION

The images can be thought, in the case of Flammarion's science popularization work, in a dynamic among instruments, real object and its representation. This "real object" is an ideal shared by the French popular education program, by the time it approached sciences speech and scientific education, movement which still been observed in the 20th century, in the constitution of scientific culture associations (NASCIMENTO, 1999). The use of photographic images can be interpreted as this "explanation of real".

The interest on the image in this work can be attributed to its evidence value. The development of photography, in the 19th century beyond being an element of proof, in the science popularization discourse brings the traces of the object observed involved by delight and emotion. There is in this edition, also an attention to show images of scientists in pictures, paintings, engravings, and in scenes of using instruments. The illustration functioning favors the sensational aerial photo images, as well as inaccessible spaces: polar landscapes, Earth or global images, images of the limits of the universe, among others. These works still can be observed today, in the election science popularization images in this science area. A relationship ever investigates how these images can be found in other sciences writing traditions, and in the science teaching. In this study, however, we introduce this theme for the discussion toward opening other possibilities for future analyzes.

DEVELOPING A MODULE ON STEM CELLS: STUDENT-TEACHERS' MEDIA INQUIRY

Vasiliki Spiliotopoulou,[1,2] *and Ioannis Papantoniou*[1,3]

Abstract: This paper studies the media inquiry of a group of Greek student-teachers which took place in the context of a science education course. Its goal was to identify media information appropriate for the introduction of knowledge concerning stem cells into school classrooms. Materials collected by student-teachers and their teaching plans are the data of the study. Findings show that student-teachers accessed a substantial number of media, mainly electronic sources. The public domain of science as portrayed in student-teachers' collected material seems to affect the kind of thinking they develop and also their teaching plans. Private stem cell banks' sites seem to be a major source of information for student-teachers, though few sources can be considered reliable. Their awareness of socio-scientific issues of this nature needs further development and evidence suggests that there is a need for more specific guidance to be included in the teacher education course activities.

INTRODUCTION

Although textbooks play a dominant role at nearly all levels of the educational system, students are also exposed to several other text-based sources of information in most subjects. There has been an immense increase in the availability of digital information sources over the last decade, with many students being exposed to easily accessible information related to study tasks. On the other hand, such an information overflow represents a challenge regarding the way in which information is processed and comprehended, and demands new approaches in classroom science teaching as well as a different role for the teachers. Proficiency in the meaningful reading of multiple texts and acquiring and integrating knowledge from a series of written documents is not supported by current school and university teaching practice.

Members of a modern society are continually bombarded with information from innumerable, often conflicting, information sources, requiring individuals to cope with challenging reading tasks on a daily basis. In dealing with such complex tasks, people need to make choices about which information to attend to and trust (Strømsø et al, 2008). A large body of this information refers to new scientific issues, such as nanotechnology, climate change and biotechnology, all related to science teaching and crucial for citizens' everyday life. The importance of taking into account such aspects in science teacher education courses is the focus of this study.

RATIONALE

Transforming the pedagogy of school science is a major challenge as two features prevail: the "collective culturally embedded notion of what it means to teach science" and the "assessment system which overwhelmingly values the reproduction of factual information as the best measure of a knowledge and understanding of science" (Osborne, 2007). As (it) has been described by National Research Council (1996), teachers' professional development comprises opportunities for intellectual professional growth, introduction to scientific literature, media, and technological resources that expand their science knowledge and experiences to access further knowledge. It has also been argued that science courses need to offer prospective and practicing teachers the opportunity to learn about science through inquiry. This perspective is based on a hypothesis. The form of professional development, including research experiences for teachers, will probably allow teachers to experience scientific inquiry in the hopes that these experiences will then translate to inquiry in the classroom. Research evidence has shown that teachers who entered the program with a more sophisticated, theory-based understanding of teaching and learning were better equipped to understand inquiry as a model and to use classroom-based inquiry throughout their teaching on completion of the program (Blanchard, Southerland, Granger, 2009).

Another goal of science teachers' programs is related to perspectives that view and support teachers of science as the representatives of the science community in their classrooms. In attaining these goals, student-teachers' scientific and media literacy are of great importance. Media is a key element in the mediation of the "relations of definition" between science, the public and the political spheres (Beck, 1992). As new links are established between citizens, scientists, politicians and media professionals, the embeddedness of science and politics has become increasingly public making science more exposed to criticism, contestation and deconstruction (Carvahlo, 2007).

Advances in biotechnology comprise social components as well as scientific components (Halverson et al, 2009) that individuals may consider while developing their opinion about the usefulness of such advances. For example, stem cell research is connected to social acceptability and also to the great economic impact of future stem cell-based therapies (Pompe et al, 2005). So, when teachers today deal in classrooms with concepts such as cells, genetic material and health therapies, they are expected to enhance their students' literacy and critical thinking on such kinds of issues that they may face during their everyday life. Student-teachers' awareness of what in fact scientific advances are, and also of the ways in which such advances are portrayed in the public domain and the media, is considered to be an important goal in their education. One of the three major roles of communication of scientific information in our society is that of popularizing information generated by the scientific community, while Journalistic Reported Versions are considered the representative genre of this type of communication, and a matter worthy of study (Yarden, 2009). Jiménez-Aleixandre & Federico-Agraso (2009) have studied how the argumentative structure of a scientific paper, Hwang et al.'s (2004) paper about human somatic cell nuclear transfer, is presented into four Journalistic Reported Versions (JRV) of it. It has been found out that the argumentative structure of the scientific paper is translated into the JRV giving prominence to the therapy claim. The apparently ostensible main claim of Hwang et al.'s paper about nuclear transfer constitutes a justification for the second claim about its therapeutic applications, for which no evidence is offered. This fact also had an impact on university students' perceptions of the summary of one of the JRV. Most of them identified both claims, nuclear transfer and therapy, citing the evidence and justifications mentioned in the JRV, which were mostly oriented to therapy.

The interest of the present study is on how a module can initiate student–teachers' thinking and actions to handle media science information, to get familiar with current knowledge and debates and to produce teaching material about a new scientifically contemporary topic, the stem cells. More specifically the following research questions are explored here: How **is** knowledge on stem cells represented in the Greek public domain as appears in student-teachers' choices of media material in order to be informed about stem cells? What are the characteristics of the selected media materials?

METHODOLOGY

The research described here refers to a university primary science education course and is addressed to prospective primary teachers. It consists of a number of modules on scientific and media literacy, argumentation and authenticity in science communication, while aspects like the nature of science and the public understanding of science are also included. The general philosophy of the present teacher education course, the design and implementation of the modules, follow a "design research" approach, that makes use of existing traditional research findings to develop some type of 'product', in the case of teacher education, programs for professional development" (Wood & Berry, 2003, p. 195). During one of the modules on media literacy, student-teachers obtain experiences while searching for media articles appropriate to be used in primary science classrooms. Examples of Journalistic Reported Versions of scientific advancements and socio-scientific issues, as well as their use with primary school students have been presented and discussed. One of the topics that was initiated and proposed as the field of inquiry concerned the stem cells. During this inquiry, students searched and selected media material in order to get informed about the topic of stem cells. The further goal was to develop awareness on the stem cell issues in order to build a teaching unit about stem cells for primary students of 6th grade. During their semester exams they had to answer a number of questions on their inquiry and teaching designs. Final products (materials and written replies) of 170 student-teachers for the exam preparation, the outcome of an independent personal media research, are the data of this study. The inductive qualitative content analysis (Mayring, 2000) has been adopted for the analysis of student-teachers' written materials and products. 445 media documents have been analyzed.

RESULTS

The analysis of media materials identified by student-teachers (documents in their portfolio) has led to the construction of a system of dimensions and categories of their characteristics, presented in the systemic network of figure 1. One dimension refers to the *number* of different materials which have been found by the student-teachers. Another refers to the *type of source* from which the information has been tapped. That means if the source is recognized as a newspaper, a magazine or a journal, stem cell banks' information, organizations/associations, wiki-sites or web magazines/sites. They have also been analyzed in terms of the genre of text that the material includes: articles, scientific articles, interviews, descriptive texts, personal experiences and advertisements. The third dimension concerns the *content* of student-teachers' selected documents. Two aspects are examined: what is involved in each document, and its purpose. More specifically, we examined whether the materials involve definitions of stem cells, their types, references to umbilical cord cells, properties, applications of stem cells in medical cases, research issues, controversies concerning moral or political issues, historical information and finally information about stem cell banks or their advertisements.

We also examined whether the main purpose of the document can be considered as offering conceptual information about stem cells, examples of research experiments, as being for medical purposes, promoting private stem cells' banks or posing the ethics of stem cells' use. The last dimension refers to the persons who are involved in the materials either as *authors* or as *interviewees*. These persons, when their identity is stated, can be doctors or researchers, journalists, stem cells banks' representatives, or individual persons who expose their experiences in blogs.

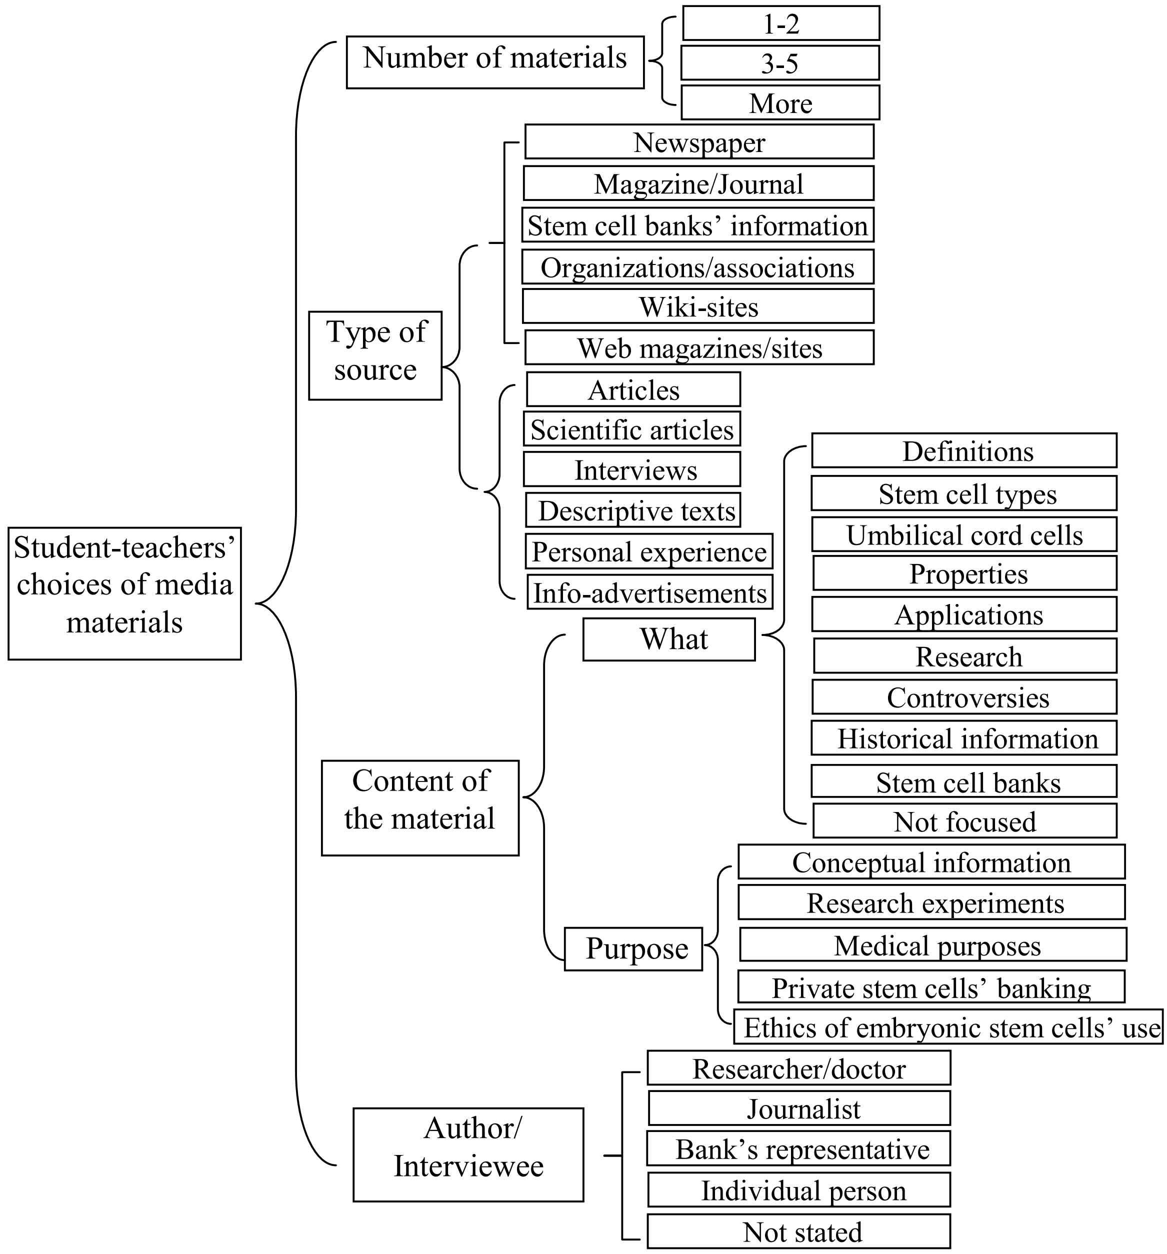

Fig.1 Systemic network of categories: characteristics of selected media material

The findings indicate that **over** one third of student-teachers' documents come from web magazines/sites (Table I), one fourth from newspapers and 14,5% is stem cells banks' information, e.g. electronic leaflets provided by private Greek stem cells banks. This last category is probably due to the fact that 20% of the world private stem cell banks exist in Greece. 11% of the documents have been selected from information, mostly electronic, of Organizations/associations, 9% from wiki-sites and only 7% from Magazines/Journals. In terms of genre, 38% are descriptive texts, 29% articles, 20% info-advertisements, 11% interviews, 9% descriptions of personal experiences/opinions, while only 3,5% are scientific articles. Very few **of** the sources and the identified texts can be considered scientifically valid.

Table II presents frequencies of categories in terms of the content of the selected materials and in terms of the author of the documents. So, the content of the identified documents refers mainly to uses and applications of stem cells (45,5%), followed by stem cell banks' information (43,5%), references to umbilical cord cells (38%), and to controversies on health issues or private versus public safekeeping (33%). 29% of the selected documents **also** contain definitions of stem cells, 24% describe stem cell types and 18% stem cells' properties.

TABLE I: Frequencies of the categories of characteristics			
Aspect		**Category**	**Percentage/ Frequency (%)**
Number of documents		1-2	55
		3-5	36
		More	29
Type of document	Source	Newspaper	24
		Magazine-Journal	7
		Stem cell banks' information	14,5
		Organizations/associations	11
		Wiki-sites	9
		Web magazines/sites	34,5
	Genre	Article	29
		Scientific article	3,5
		Interviews	11
		Descriptive texts	38
		Personal experience/opinion	9
		Info - advertisement	20

Finally, 16% of them include research issues or evidence, while 13% include historical information. In terms of the purpose of each document, in 43,5% of them medical purposes are involved, 40% aim to be conceptually informative, in 27% the socio-ethical issues on private stem cell banking are exposed, in 24,5**%** the scientific aspects are exhibited through the description of research experiments and finally a small percentage, 5,5% aims to expose the ethics of embryonic stem cell use. Finally, in 27% of the cases the documents are written by a journalist, in 19% by a researcher or doctor, in 14% by individual persons and in 13% by a stem cell bank's representative.

CONCLUSIONS AND IMPLICATIONS

Activities with media involved in the teacher education course seem to motivate student-teachers' interest and engage them in conversation with the scientific advances in stem cells as these appear in popular media culture. Their inquiry took place mainly through internet searches. Research issues or scientific articles are a limited proportion of their portfolios' documents. It is worth noting that the umbilical cord cell type is a dominant theme in the selected documents, while reports on other stem cell populations such as hematopoietic stem cells, neural stem cells, osteoprogenitor stem cells etc, which have also demonstrated potential for clinical applications, are limited. This in connection with the prevalence of references to the stem cell banks represents the widely spread public discussion on these issues in Greece and shows how the public media support and spread this discussion. This claim is supported by the fact that the aforementioned controversies are related mainly to socio-ethical issues on private stem cell banking, while the issue of ethics concerning embryonic stem cell use is almost absent.

The obvious purpose of these reports is to inform the audience of the medical benefits of stem cell research. The medical aspects play an influential role for the citizens as it is a sensitive issue for their lives and many studies have highlighted this tendency in students' understanding and discussions (Halverson et al, 2009; Halverson, 2011; Molinatti, 2011).

TABLE II

However, the hidden purpose is to persuade the readers about the importance of keeping the umbilical cord cells of newborn children. Parents face the dilemma of having to choose whether to avoid the high cost of stem cells banking and thus miss out on possible future benefits that their grown up children would have if they kept their umbilical cord stem cells during their birth. It is noticeable that in Greece the majority of stem cell banks are private, while the public services are not developed satisfactorily. The findings reveal that the public domain of science concerning stem cells in Greece is mainly dominated by stem cell private banks' sites, something that poses questions about the neutrality of such information. Of course science in the media is not at all like science in the textbook. It is shaped by media practice and codes of behaviour, influenced by commercial goals and the values of those who construct the news agenda and is responsive to the interests of the audience (McClune & Jarman, 2011). Moreover, it is shaped by local communities' goals, values, and priorities.

There is no clear evidence that student-teachers' critical media literacy has been developed to a satisfactory degree. Their engagement, however, with all this information has triggered an inquiry stance towards media information and its utilization for classroom learning and seems to support critical pedagogy. Moreover, through this design-research we discerned different aspects of student-teachers' involvement with media; this experience offers insight into how to guide student-teachers' use of the public domain of science more effectively in their learning about scientific advances and in using this information in their teaching plans. Their perception and attitudes with regard to this domain, as appear through evidence from the other activities they had to build, are significantly influenced by representations of scientific knowledge conveyed by the press and other mass media. Making the assumption that student-teachers' material may be a kind of representation of the information available on stem-cell issues in the Greek public domain, this article argues that the discursive reconstruction of scientific claims in the media is strongly entangled with social and commercial standpoints. Media information needs to be handled in a critical way by educators and teachers, as its neutrality is questionable. As Carvahlo (2007) claims, deciding what is scientific news, i.e. what the relevant “facts” are, and who are the authorized “agents of definition” of science matters is a crucial issue. The representation of scientific knowledge in the public domain has important implications for evaluating scientific applications in everyday life and teachers’ responsibility for the education of the critical faculties of each citizen is urgent. Awareness gained from the present research can lead to the further improvement of the module. Further experience is necessary in order to gain insight into how to guide student-teachers’ use of the public domain of science more effectively in their teaching.

"ASPECTS OF TECHNOLOGY" IN SCIENCE FICTION TEXTS – SCIENCE FICTION IN SCIENCE CLASSROOM: AN EMPIRICAL STUDY

Ioanna Stavrou[1] *and Constantine Skordoulis*[2]
[1] Ph.D Student
[2] Professor of Physics and Epistemology of Natural Sciences
[1, 2] National & Kapodistrian University of Athens,
Faculty of Primary Education, Department of Physical Science, Technology and Environmental Studies

Abstract: This study refers to the research conducted with primary school students examining whether they can identify the issues raised by the ethics, moral and political aspects of Technology through analyzing science fiction texts (short stories). In addition, we examine whether they can write science fiction stories of their own raising the above mentioned issues.
The research was conducted with a sixth-grade primary school class of 22 students over a period of six weeks in two-hour sessions, where students read and analyzed science fiction short stories and wrote science fiction stories of their own.
Our data (worksheets and science fiction stories by the students) were analyzed with Qualitative Content Analysis. Our analysis shows that the students can identify the elements of the text referring to the positive and negative aspects of Technology concerning the ethical and moral issues related to society. The students are at ease writing science fiction stories in which societal, ethical and moral aspects of Technology are presented, especially, as far as the use of Technology in the solution of environmental problems is concerned.

Keywords: science fiction, critical considerations (deliberations) of technology

INTRODUCTION

This study refers to the research conducted with primary school students examining whether the students can identify ethical, moral and political issues related to Technology raised in science fiction texts.
Science fiction texts were chosen as their plot often involves Science and Technology, as well as the impact that these have on society and the environment. The extrapolation of the "what if…" of science fiction texts does not violate scientific principles, but relies on them to guide thought experiments through to possible consequence (Czerneda, 2006).This process makes us concerned with current technologies enabling us to observe the possible manifestations of scientific progress and to experience and appreciate the many ways this may impact upon society and environment (Stavrou & Skordoulis, 2008). It can also serve as a focal point for discussion about our attitudes, perceptions, hopes and fears about Science and Technology (Berne, 2008). Additionally, science fiction texts highlight the ethical and policy issues raised by Science and Technology and provoke controversy and debate about possibilities and ramifications for humanity. The narrative elements of science fiction literary genre are used in the discourse of Science and Technology to bridge the gap not only between what is technically possible today and its inflated promises for the future but also to probe into the ethics about Science and Technology. Thus, science fiction could be used as a tool with which students might navigate the ethical and societal dimensions of technological terrain (Berne, 2008, Miller & Bennett, 2008). At its most powerful, science fiction has the potential to be not just story-telling but an inquiry into the human dimensions of technological futures

(Miller & Bennett, 2008). Thus, can take advantage of the popularity of science fiction to engage students more broadly in deliberations about technology (Miller & Bennett, 2008).

As Deery argues science fiction performs “a vital social function, which is to offer a testing ground, a thought experiment, where the social consequences of Science and Technology can be extrapolated in an intuitive, holistic and empathetic manner”, thus offering “humanistic-cultural” as well as political dimensions to Science Education (*as cited* Dritsas, 2007). Moreover, as science fiction is so often taken to be the expression of political opinion or ideology of the scientific and technological society aimed at presenting alternatives to social condition, it functions as thought experiment and critical discourse which can also bring more skepticism about politics, ideologies and epistemological certainties in the context of Science Education (Gough, 2006, Griffiths, 2009, Weinstein, 2009). This new socio-literary techniques, inspired by science fiction could offer significant contributions to the governance of new and emerging technologies by improving the capacity to reflexively assess the social dynamics of socio-technical systems (Miller & Bennett, 2008)

This study is a part of a wider research project whose main aim is to examine the way science fiction texts can be used as supplementary educational material in a cross-disciplinary context in primary school (Stavrou & Skordoulis, 2008, Stavrou & Skordoulis, 2010).

METHODOLOGY

Due to the fact that this study is part of a wider research project aiming at examining whether science fiction texts targeted at adult readers could be used in the context of educational process in primary school, we designed and conducted the following Case Study.

Case Study Protocol

Research Questions

• Whether students can identify the ethical, moral and political issues related to Technology raised in science fiction texts.

• Whether students can write science fiction stories, in accordance to science fiction conventions, raising the above mentioned issues.

Sample

The research was conducted with a sixth-grade primary school class of 22 students (12- year olds). The majority of them came from high-income and high education families.

Our research, consisting of six two-hour sessions, covered a period of six weeks in a cross-disciplinary context.

Implementation

Firstly, students were asked to articulate definitions of science fiction. Then, they discussed upon science fiction definitions given by the critics of the genre and they were asked to identify the elements unique to the science fiction genre according to these definitions.

Thereafter, students read and analyzed the following science fiction short stories:

«Memorial» (1946) by Theodore Sturgeon

«The King of the Beasts» (1964) by Philip Jose Farmer

«The Dragon XXXX» (1960) by Stanislaw Lem

«Computer Virus» (2001) by Nancy Kress

The above texts were chosen on the basis of the following criteria: a) they were written by acclaimed and awarded science fiction writers b) they refer to socio-scientific controversial issues and, in particular, to contrasts and conflicts or different approaches emerging from

different speculations on technological advances c) Science and Technology are depicted as human activities interacting with society.
Having read and analyzed each text, students had to work on a worksheet on the “scientific context” of the text, as well as the characters, their actions, the facts and the plot. The worksheets were designed in order for students to study not only the basic elements of the story, such as the theme, plot, setting and conflict, but also to highlight any technological, societal and/or ethical, moral and political issues as well as Technology versus society issues that were raised in the stories.
In the next stage, students were asked to write their own science fiction story according to particular instructions, in order to examine whether students were able to write science fiction stories of their own and, at the same time, whether they were able to raise the above mentioned issues in their stories. The science fiction story was assigned as an individual homework task. Finally, the students were asked to evaluate their own stories by use of a questionnaire, in order to become aware of the ‘scientific context’ of their stories.
Our data (worksheets and science fiction stories by the students) were analyzed in accordance with Qualitative Content Analysis.

RESULTS

Worksheets

The students were able to identify the elements of the text referring to the positive and negative aspects of technology concerning society and the environment. The majority of them mentioned the ‘dual use’ of Technology. For instance, when analyzing the “Memorial” text, the majority of them focused on the use of Nuclear Power for peace and its military use (nuclear weapons). They also mentioned the problem with nuclear waste even when it is used for peace. It is worth mentioning that a majority of them associated the military use of Nuclear Power and Technology with politics.
Moreover, they focused on the dilemmas faced by the scientist characters of the stories concerning the impact of the use of Technology (Nuclear Technology or Biotechnology).
Another point of focus was on the ethical and moral issues regarding the applications of Technology. In particular, when analyzing the text “The King of the Beasts” the students questioned the ethical or moral right of the scientists to clone a human being or even an animal. On the other hand, in both the stories “Memorial” and “King of the Beasts” the students articulated the view that only a scientist could deal with ethical and moral issues concerning Science and Technology just because *“he is a scientist”*, that is, a special human being.
In addition, they associated the use of Technology to matters of politics and power. In the text “The Dragon XXXX” the majority of them focused on the use of Information Technology and Computer Technology for world domination on behalf of politicians. Moreover, they were able to identify the positive and negative aspects of Technology as well as the impact of Technology on society, even when the text dealt with subjects the students were not familiar with.

Science fiction stories written by the students.

The students were able to write short science fiction stories of their own, in accordance with the genre’s conventions. Despite the fact that they found it difficult to elaborate on the dilemmas faced by the scientist characters of their stories they were able to write about the

variant aspects of Technology as well as the impact of Technology on society and the environment.
In several students' stories Technology was used in the solution of environmental problems, or in many cases, in the solution of problems faced by society (the hole in the ozone layer, cleaning the polluted seas, medication for the poor).
In addition, in several stories there were concerns about issues relating to ethical and moral aspects of Technology, as in the case of stories where cloned or mutated humans or even robots revolted against Technology itself.
Ultimately, in all stories the main character was a scientist, being the only person capable of giving solutions to any kind of problems.

CONCLUSIONS

Although the students were not familiar enough with written science fiction, they were at ease differentiating and identifying the ethical, moral and societal aspects / issues of Technology, especially when presented with texts referring to subjects familiar to them, such as Nuclear Power, Biotechnology, or texts in which the main character was a scientist.
As far as their own stories are concerned, the belief that Technology can be used in the solution to any problem faced is expressed in all stories. Moreover, the image of the scientist who has the ability to deal with and find solutions to all problems or issues prevails in all of them.
Because of their engagement with science fiction texts students were able to ask where humanity could possibly be led to with Science and Technology, and how these might affect the social, moral, and environmental conditions of human life. Thus, science fiction could be used, in order to enhance Education for Values, in Science Education.

Abstract: This paper shows the results of discussions of university level students who worked in small groups during the decision making process on an open-ended environmental problem. We have studied the decision making process of each group bearing in mind the steps of the normative framework. The process undertaken by one of the groups stands out as the students are capable of changing their initial option after having born in mind a criterion contributed by a companion and that had not appeared initially. This opinion has been decisive in evaluating the different alternatives and has been key to the change of position of various components of the group, something that is not usually the norm. We have also considered the difficulties another group had coming to a decision, as they could not deal with the disadvantages that all alternatives showed. It is concluded that the normative framework is a powerful tool which can help students in their approach to decision making using pre-formulated steps.

Keywords: Decision making, open-ended socio-scientific problems, environmental education

BACKGROUND, FRAMEWORK AND PURPOSE

Admitting that to educate for a change in society is one of the goals of Environmental Education, and that dialogue, negotiation and consensus are the basic mechanisms for the resolution of the conflicts, the development of action competences of our students will imply learning these procedures.

Training in the analysis of socioenvironmental conflicts, in the debate of alternatives and in the argued decision making for their resolution are, therefore, some of the goals to prepare our students for social transformation. From the point of view of environmental educators, we are interested in analyzing the communication established in the classroom to identify the learning processes and its obstacles.

During these last two decades the research based on the analysis of the decision making and the argumentation on socioscientific issues have increased and have diversified as regards the object of study, since now besides contents or scientific aspects, they appear other series of dimensions like social ones, psychological ones, ethics and pedagogic ones and, also, investigations in which the quality of the argumentation produced is evaluated and investigations to find the way of designing environments that favour argumentation.

RATIONALE

The process of decision making on open-ended socioscientific problems followed by students has been investigated from diverse points of view. We will comment those who have analyzed the process comparing it with normative frameworks (Kortland, 1996; Ratcliffe, 1997). According to these frameworks the first step implies assuming the task of taking the decision, next bearing the different options in mind, establishing criteria, seeking for information to evaluate the alternatives and, finally, making a decision (Janis and Mann, 1977).

But in everyday life it seems that we usually do not follow these steps, and we somehow start to evaluate the options at the same time that we put them on the table and we even, on some occasions, make the decision at the beginning of the process, which biases the subsequent process, since we tend to take into account only the information that supports the decision taken.

Ratcliffe (1997) developed a normative framework of several steps that made her students follow to decide on several situations. As Kortland (1996), she concluded that the students were in fact evaluating the alternatives while they were identifying the criteria that would guide their choosing process.

With this work we try to know how is the groupal decision making process of university students referring to a normative framework modified from Janis and Mann (1977), and studying if the students establish initially the criteria that will guide their process or follow a process biased by an option taken beforehand on an environmental decision making task.

METHODS

The design of this investigation is based on a similar study conducted with secondary students (Jiménez-Aleixandre, Eirexas and Agraso, 2006), who were presented with a case in which they needed to decide upon a heating system, basing this decision on economic and ecological criteria. In our own design, subjects were presented with the same problem: we had students select a heating system from among five possibilities without providing them with selection criteria. In addition, we developed a 23 pages dossier, containing information about the characteristics of the different energy sources, the environmental problems of their use and various data about the economic costs and emission of gases and particles. Besides, the students had six articles about the same issues. We tried to make this dossier as complete as possible, since it would be the most important source of information that would be available to the students.

The study took place in one section of the elective course 'Environmental and informal education' in the Social Education degree programme over the course of four 1½ hour sessions in May, 2004. The first three sessions were dedicated to cooperative work in small groups that involved reading the information and making decisions and the fourth session was dedicated to sharing results.

25 students participated (23 women and two men). Subject ranging in age from 18 to 23 years old were divided into the four groups.

We based this design on the idea of forming learning communities (Brown, 1992). Since students were placed in small groups to work together, they helped each other to learn. Furthermore, students who work in groups tend to demonstrate more positive attitudes and increase their self concept for the study when compared with students who are not grouped, demonstrating numerous changes associated with the establishment of collaborative learning environments (Oliveira and Sadler, 2008).

At the beginning, we simply gave each group a handout describing that their mission was to decide upon a heating system for a future building from among the options of diesel oil, natural gas, propane, bio-mass and electricity. Once the students offered their initial opinions, they were provided with the informative dossiers.

The first three sessions were audio-recorded and the fourth was video-recorded. Each group also generated reports in the form of session diaries, which were also collected.

The research falls within the interpretative methods of research (Erickson, 1986) that try to interpret the meaning actors give to their actions. The first author was the teacher of the group, and she and the second author were participant observers during the task. The results presented here are based on the oral discussions of three groups during the three first sessions as they arrived at a decision concerning the selection of an energy source. The transcript of the fourth group's discussions was lost due to technical issues. Students have all been assigned gender-appropriate pseudonyms. The pseudonyms assigned to Group A students all begin with the letter 'A', those of Group C students begin with 'C' and those of Group J students begin with 'J'. Group A was composed of six women, Group C consisted of four women and one man, and Group J included six women and one man.

The first step in the normative framework taken as reference consists of discussing the different solutions for a problem. In our case, as these options were determined in the task, this step was not taken into account. To make the analysis, we read all the statements (interventions) made by the students and we differentiated those that were related to the decision making process and those that were not. Then we proceeded with the identification and categorisation of the interventions related to the decision making: developing criteria, searching for information, evaluating alternatives and decision making.

In order to validate the identification and categorisation of these interventions, the two first authors conducted the analysis of Group A together and the analysis of Groups C and J separately and compared the results, reaching a 90% of agreement. The disagreement were discussed until a consensus was reached.

RESULTS

Initially, before having any information, all three groups opted for natural gas, although they admited that they needed more information to make a more informed decision. Table 1 presents the percentage of interventions dedicated to the different steps in the process of taking a decision in the three groups.

As can be seen, Group A dedicated a high number of interventions to the proposed task, especially to the evaluation of alternatives. Some members modified their initial choice based on the information provided in so far as they presented two different positions within the group (two support electricity and four natural gas), trying to persuade each other.

What happens is that one student supporting electricity (Arrate, line 533) refutes other student´s justification by saying they have to take next generations into account, which we have interpreted as using sustainability as a criterion (Uskola, Maguregi and Jiménez-Aleixandre, 2010).

532	Ainara:	(…) I also choose natural gas, (…). Natural gas is more cost efficient, more comfortable and well, although there are few resources, well, damn, there are still years left, right? And that's it, well, I don't know.
533	Arrate:	It's that, don't just think about the years that you're going to be here, think about those who will come later.
534	Ainara:	Sure but...
535	Amaia:	Sustainable development

From this time foreward the two options are evaluated on the basis of this criterion, leading three more students to support electricity. We could say that at individual level, students changing their mind followed the normative framework, while the students that where previously defending electricity don´t, as they have raised a criterion that falls in line with the decision they have already taken. These different individual results in Group A may arise because the normative framework usen by Kortland (1996) and Ratcliffe (1997) is quite linear and valid for one individual. We consider that this process that individually gives different interpretations, constitutes a good groupal process, as it has been the group who has created a criterion beyond the available information and who has adopted that criterion as a keystone in the process.

It is not usual that students change their mind during the process, as they usually take into account the information that fits with their choice (Kortland, 1996). Nevertheless, Jiménez-Aleixandre and Pereiro-Muñoz (2005) and Simonneaux (2001) found changes and evolutions in choices of students discussing socioscientific issues. In this case, the change has been produced by the introduction of a new and unexpected criterion, showing the seriousness of approach of the group on the proposed task, and also the open-mindedness of the students that change their mind by considering a criterion that did not favor their option.

The decision making process in Group C fits the normative framework. Since the initial stages of the task they hold that they do not want to contribute neither to the depletion of the natural resources nor to an increase in social differences. They search for information and evaluate the alternatives in the basis of the agreed criteria until they make their decision.

84	Carmen:	(*with respect to fossil fuels*) So these three pollute a whole lot. Well, at the moment we don’t like these, right?
85	Coro:	Right, but we don’t like…
86	Carlos:	… a level that is ecological
87	Carmen:	And economic level?
88	Carlos:	Well
89	Carmen:	And at a social level

The process of Group J is quite different. It is noteworthy that until intervention in line 779 (among a total of 799) there is not a choice to support one of the alternatives, as they discard all of the options when they know about their disadvantages. Group J is the one that dedicates less time to the task (Table 1) and they continuously complaint for lacking information to make the decision.

489	Jesica:	But biomass sounded us fantastic, but then...
490	Jon:	Solar panels.
491	Jesica:	But then we realized about disadvantages we discarted … Maybe biomass.
492	Julia:	We lack information.

This is a situation found also in other investigations (Hogan, 2002; Kolstø, 2006) and named *defensive avoidance* and that can be interpreted as not even taking the commitment to make a decision, a previous step to start the process (Janis and Mann, 1977).

Steps of the Decision Making Process	Group A %	Group C %	Group J %
1- Developing criteria	1	2	1
2- Searching for information	20	21	34
3- Evaluating alternatives	49	36	4
4- Decision making	5	10	4
Total	75	69	43

Table 1: Proportion (percentage) of interventions dedicated to the steps of the Decision Making Process.

CONCLUSIONS AND IMPLICATIONS

It should be noted that the students who took part in the study show a high decision making competence, demonstrated by their willingness to consider the advantages and disadvantages of the alternatives and their requirement of having information available before making a decision (Ratcliffe, 1997). This can be related to the age and maturity of the students. Besides, they show a high level of commitment to the task, dedicating a high proportion of their interventions to the decision making process.

It is noteworthy to highlight that none of the three groups has mantained their first choice, natural gas. This draws us to the conclusion that both the available information as well as the interactions among the students have been key and more important that the previous preferences, which would fit to some extent to the «*valence distribution model*» sociologic theory, confirming Aikenhead (1989) hipothesis in that in the cases of group decision the most important factor to consider is the discussions among the groups. We consider noteworthy the fact that the option changes of the members of one group are due not only to new information but also to the introduction of a new criterion by one student which was not previously taken into account.

On the other hand, it is worrying the situation in one of the groups that can not cope with the fact that there is not a perfect solution, that all of them have disadvantages. We think that there are several things we could do in a future activity to prevent this situation. One is to use the potentiality of the normative framework (Kortland, 1996) making students more conscious of the steps they should follow. Another one is to work with students about more authentic situations in which the intrinsic uncertainty and complexity of science and everyday life arise.

Although we acknowledge the limitations of this study, we think that this kind of learning contexts can favour the development of decision making competence and critical thinking, recognised as important objectives of science education in the Budapest Declaration (UNESCO-ICSU,1999) and more recently in the OCDE Pisa Project (OECD-INECSE, 2006).

THE CONTRIBUTION OF "POPULAR" BOOKS TO THE INFORMAL LEARNING OF CHEMISTRY

Ana S. Afonso[1] *and John K. Gilbert*[2]
[1]University of Minho, Portugal
[2]King's College London, U.K.

Abstract: This study aims at identifying and categorizing books based on chemical ideas for a general audience, at analyzing the text understanding and interest in the themes covered in the book by a non-specialist audience, and at identifying characteristics of the text that can enhance reading with comprehension for that group of individuals. In order to attend to these aims, the catalogues of 59 major publishers, publishing books in Portuguese and English, were searched and 145 books currently available in the market were identified. These books were then grouped according to their themes. In addition, 17 students, with no extensive background in science, were invited to select a book from one of the categories, to summarize it, and to evaluate it using a general framework provided to them. Results show that most of the books are about "biographies of chemists" or about "particular chemicals", and that readers became interested in some themes covered by the book. An overall understanding of the text was not achieved; in particular, aspects concerned with nature of science were not understood. The readability of the books was constrained by features of the text.

Keywords: books for general audience, comprehension of text, informal science education, learning of chemistry.

INTRODUCTION

"Popular" chemistry books: a partway to chemistry literacy

Chemistry is embedded in all aspects of life; from food preparation, cosmetics, cleaners, and waste disposal to textile preparation. Although the idea of "chemical-free" life is a myth, several misconceptions about what chemicals are and do are spread among citizens (e.g. chemicals are unsafe, cause pollution, and can be avoided by special diets and soaps, synthetic chemicals are causing many diseases) and influence their decisions about health, lifestyle and social policies (Hartings & Fahy, 2011). Consequently, there is a need to improve the levels of chemistry literacy among citizens so that they can move from lower levels of chemical literacy, in which chemistry can inform proper decisions in daily life (i.e. practical literacy), to higher levels of literacy in which individuals can participate in social debates involving chemical sciences (i.e. civic literacy) or appreciate chemistry as a major intellectual activity (i.e. cultural literacy) (Shwartz, Ben-Zvi, & Hofstein, 2006).

Informal chemistry education plays an important role in engaging citizens with chemistry, in particular adults who are no longer in the educational system. Informal chemistry education can be characterized by being voluntary, learner-led, non-assessed, and covering a diversity of contents. It can also be promoted in different settings, ranging from science museums, television, Internet to print. These modes of communication have been successful in engaging and educating citizens in science broadly. However, in some of these informal settings, such as television or science museums, few chemistry ideas are covered. Print has been one of the main modes of communication used by USA adults to engage with science (Masciangioli, 2011). In particular, in the last thirty years there has been a publishing boom of science books for a non-specialist audience (Turney, 2001). Yet, the role of these books in promoting scientific literacy, in particular chemistry literacy, is unclear due to a lack of systematic studies focusing on this mode of communication.

Chemistry books for non-specialists can be called “popular” chemistry books. They can be defined as books based on chemistry ideas, printed in a large scale for a general audience who are interested in improving their understanding of a particular theme and in being entertained at the same time. General guidelines have been proposed for writing “popular” chemistry books so that they can have an impact on improving chemistry literacy (Emsley cited in Masciangioli, 2011): choose a topic being that is something new, something that answers previous problems, something that overturns beliefs, something that impacts people’s lives; avoid of technical terms but if they are necessary they need to be explained; avoid chemical formulas; neither overestimate the public’s familiarity with the topic nor underestimate their intelligence; include human interesting information; and make chemistry visible by giving it a critical role in stories.

Reading with comprehension

A text can be processed at two different modes: either as a set of propositions (i.e. a description of a text itself, retaining its structure) or as a mental model. Reading with comprehension requires constructing a mental model of what the text is about. A mental model of a text is an adequate mental representation of the elements of the text (e.g. events, states, objects, and protagonists) and their relations (e.g. causal, temporal, and logical) that are explicitly mentioned or that can be inferred from the text. A model of a text is personal, is guided by the reader’s goals, is continuously updated and constructed during reading, and corresponds to an interpretation of a particular text in a particular moment (Kintsch & Rawson, 2005; van Dijk, 1995). Thus, a mental model of a text is a representation of the situations described by a text, rather than a description of the text itself.

Constructing a mental model implies the simultaneous activation of top-down (e.g. retrieval of prior knowledge) and bottom-up (e.g. recognition of “data” from the text) processes. This is an easy task for skilled and knowledgeable readers but a problem solving activity for non-skilled or less knowledgeable readers. For the former readers, top-down processes ensure that text information, consistent with their prior models and expectations, is integrated in their mental structure; while the bottom-up processes call the readers’ attention to novel information. It is expected that skilled and knowledgeable readers can not only select, synthesize and organize the main ideas in a coherent summary (i.e. provide an overall understanding of a text) but also build a mental model that goes beyond a literal interpretation of the text by making predictions, mental imagery, and creating links with prior experiences. For less knowledgeable readers, the activation of prior knowledge is poor and inferences from the text are difficult to perform. This results in a superficial integration of the new information into their existing mental structures. In an extreme situation, top-down processes may dominate reading, resulting in inferences based on prior guesses, oversimplifications and processing of irrelevant information. Consequently, misreading will occur and an inadequate mental model will be created (Adams, 1980; Kintsch & Rawson, 2005).

In this constructive process of meaning, different factors influence the readers’ processing of a text, namely (Irwin, 1983):

- the reader's individual characteristics: Who is reading? Attends to the reader's prior knowledge about the topic, emotional attitudes towards the topic and the reading task, and reading skills;
- the reading material itself and its individual characteristics: What is being read? Refers to micro-structural features (e.g. world familiarity, sentence length, inter-sentential coherence); macro-structural features (e.g. summaries of the main points clear organizational pattern of the text, form of the text – expository, narrative,…); and elaborative features (e.g. analogies, pre and post-reading questions, examples);
- the situational characteristics: Why, when and where are they reading? Concerns the purpose of the reading task and the social, emotional and physical environments.

A major challenge consists in finding an appropriate match between the reader and the reading material. The reading material is a channel of communication between the writer and the reader and writers need to take decisions on the form and content of the text by making considerations on a given audience. In the light of the literature, this study aims at:

- Identifying and categorizing the "popular" chemistry books that are currently available in the market
- Analyzing the text understanding and interest in the themes covered in the book by a non-specialist audience
- Identifying characteristics of the text that can enhance reading with comprehension for that group of individuals.

METHODOLOGY

In order to identify and categorize "popular" chemistry books currently available in the market, the abstracts of "popular" chemistry books, published in English or Portuguese, were searched in the catalogues of major publishers. 145 books, identified in 59 publishers, were then grouped according to their main themes. In addition, 17 undergraduate Portuguese students of education with no extensive background in science were invited to select a book from one of the categories of books created, to read it from cover to cover, to provide a summary of the texts and to evaluate the books. The readers' choices were confined to books published in Portuguese. Yet some of them were translations of books originally written in English or French. Since situational characteristics affects reading outcomes, a list of general aspects that students should have in consideration when evaluating the books were provided to them. These aspects, based on the literature on text comprehension, include: the interest and the appeal of the book; the chemical ideas included in the book; the relevance of the information provided; specific features of the text; the overall written style; and the way chemical knowledge is produced. In addition, 11 students, who produced unusual or incisive evaluations, were interviewed. The data from the books' evaluation were analyzed by using the literature on "reading with comprehension" as a framework.

RESULTS

Popular chemistry books

As can be seen from Table 1, most of the books were published in English, most of the authors were male, and most of the books are included in the categories "biographies of chemists" and "particular chemicals". Although less frequent, some books fit into the categories "chemical cookbook/hands-on chemistry", "foundation ideas in chemistry", "fiction with an emphasis on chemistry", "use of chemistry in other disciplinary fields", "history of developments in chemistry", and "chemistry in everyday life".

Table 1: The language of publication, authors' gender and categories of "popular" chemistry books (n=145)

"Popular" chemistry books		f
Language	Portuguese	36
	English	109
Author's gender	Female	22
	Male	123
Category	- Chemical cookbook/hands-on chemistry: describe phenomena and reactions that can be safely explored by readers	4
	- Foundation ideas in chemistry: deal with the core ideas of chemistry	9
	- Fiction with an emphasis on chemistry: present chemistry embedded in a fictional story	9
	- Use of chemistry in other disciplinary fields: discusses the contribution of particular chemistry ideas to research and development of other disciplinary fields	10
	- History of developments in chemistry: conveys how chemistry emerged and developed over the years	17
	- Chemistry in everyday life: emphasize the contribution of chemistry in daily life and social life	18
	- Biographies of chemists: recount the life and time of a chemist and his/her contribution to chemistry	38
	- Particular chemicals: focuses on the chemistry, applications and implications of particular substances and chemical species	40

Comprehension of the text and factors affecting it

In spite of the diversity of titles of the books selected by readers (Table 2), the data show that reading with comprehension was a difficult task for them (Table 3). Most of the readers' summaries of the books are descriptions of the text itself or parts of it, maintaining the structure of the book in their summaries. Few readers (two) built mental models of their texts, and they only reflect an overall understanding of the text. Thus, for the majority of the readers, the reading process seems to have been restricted to decoding of individual idea units and sentences (Irwin, 1993).

Issues on the nature of chemistry (NOC) were not valued and understood by readers. Their views on NOC reflect fragmented and naïve understanding of scientific enterprise and scientific inquiry, as the following example illustrates:

> "Experiments in chemistry result from observing the world. They are the grounds for building theories which are sometimes incompatible. Sometimes, scientists steal researches from their peers. This book mentions the pressure that scientists feel to publish. However, in order to publish scientists need to submit their papers to peer review" (Reader 2, *Water*)

Two reasons may explain this finding: readers may hold strong misconceptions about the theme, and aspects on the NOC are scattered along the text and not explicitly mentioned. The former reason may guide readers to select only the information presented in the text that support their beliefs on NOC. The latter reason may restrict the readers' opportunities to critically reflect on their views on NOC and to move towards acceptable conceptions, due to their difficulty in selecting, synthesize and organize the main ideas in a coherent summary.

Table 3: Readers' comprehension of the text (n=17)

Comprehension of the text	f
Bellow descriptive mode	2
Descriptive mode	13
Mental model mode	2

Several features of the text were pointed out as enhancing understanding. They include: 1) elaborative features, namely illustrations of mechanisms or drawings; analogies that employ familiar analogues; and adjunct questions; 2) macrostructure features, such as presence of sub-headings; and 3) microstructure features, particularly explanations of scientific vocabulary (Table 4).

Table 4: Comments on features of the text that were perceived as affecting understanding

Comments	Aspects mentioned and examples of response
Elaborative features (n=23)	• Illustrations “The images helped me to understand the descriptions presented in the text, allowing a more concrete idea about the objects that are mentioned.” (Reader 13, *Oxygen: A Play in 2 Acts*) • Analogies “There are some analogies that support comprehension. For example ‘a living organism is like a chemical factory’ (Reader 14, *Opportunities in chemistry: today and tomorrow*) • Adjunct questions "Questions are also present in the majority of the chapters, which is useful because they hold the readers’ attention, involving them with the text and leading to self-questioning.” (Reader 15, *Our stolen future: are we threatening our fertility, intelligence, and survival?)*
Macro-structure features (n=27)	• Sub-headings “The book organization around themes and sub-themes contributed for organizing mentally the information understood for each theme.” (Reader 4, *Magic molecules*: *how drugs work*)
Micro-structural features (n=10)	• Scientific vocabulary explained “The author provides several definitions that enhance understanding, e.g. on p. 51, the author says that: ‘I found a huge demijohn of technical benzene, at 95 percent purity. Manuals prescribed rectifying it and then putting it through a final distillation in the presence of sodium. To rectify means to distil it by fractions’ (Reader 10, *The Periodic Table*)

Interest in the themes covered by the books

Although sustained interest in the themes covered by the books was low, readers experienced motivation and interest in some sections of the books. Interest typically arises from reading a synopsis of the book that includes information about the importance of a theme and attends to reader’s interests and non-expertise on the theme. Interest in a given part of the book can then be raised, depending on whether or not the text matches the information provided in the synopsis; the themes covered are linked to reader’s concerns/needs/interests; and the author avoids specialist language. An example is:

> “The synopsis is appealing because it focuses on the fundamental aspects of the book and mentions that it is appropriate to the general public. It called the readers’ attention to the importance of reading the book without involving them in a scientific and complex reading. [After reading the book] I was interested to learn about some themes, i.e. recreational drugs or cancer. The theme “recreational drugs” was of interest to me because it is a contemporary theme that we face in our everyday life, mainly in clubs. Similarly, I was interested in the theme “cancer” because one of my family members suffered from that disease. On the other hand, in spite of the cutting edge research on the theme “gene-based medicine”, I was not interested in the topic. It is very complex and is not clearly related to my everyday life.” (Reader 4, *Magic molecules*: *how drugs work*)

CONCLUSIONS

The results of the study suggest that those who only read Portuguese will have restricted opportunities to develop their chemical literacy through “popular” science books, since these are scarce. There is a need to stimulate female chemists to write "popular" science books. Finally, more book titles on "fiction with an emphasis on chemistry", "chemistry in other disciplinary fields", and "chemistry in everyday life" are needed. Books on "fiction with an emphasis on chemistry" contain narrative, which is a key element in science communication (Stocklmayer & Gilbert, 2002); books on "chemistry in other disciplinary fields" and "chemistry in everyday life" can be successful in raising cultural and practical literacy.

For less knowledgeable readers, reading "popular" chemistry books with comprehension may be enhanced when they include: a) elaborate features (e.g. analogies with familiar analogues, drawings, illustrations of mechanisms, pictures, and pre- and post-reading questions); b) macroscopic features (e.g. sub-headings); c) microscopic features (e.g. explanations of scientific terminology). In addition, understanding NOC requires an explicit approach to the issue as already pointed out by (Khishfe & Lederman, 2007). Comprehension and interest are related (Irwin, 1983). Arising and sustaining the latter can be facilitated by including frequent and explicit links between the theme being addressed and the interests/needs/concerns of the readers, and by keeping a tied continuity between the synopses and the different parts of the book.

BIOCENTRIC REASONING IN CHILDREN: IMPLICATIONS IN SCIENCE AND ENVIRONMENTAL EDUCATION

[4]Lisbon Higher School of Education, Portugal

Abstract: This study aimed to verify the incidence of biocentric reasoning (centred on the welfare of the animals) in 91 children, aged between 8 and 10, attending the 3rd and 4th years in a primary school of Lisbon, Portugal, and is the continuity of another study promoted by the authors. To do that, a questionnaire was applied, inquiring about the type of places where the children contact with animals and their opinion about the human behaviour in three different situations involving animals (dilemmas). The results have shown that the majority of children had a small contact with natural and semi-natural places, and the majority only went to places where nature is managed, like zoos and similar parks. This experience seems to be responsible for inappropriate ideas about zoos, considered by some children the ideal place to keep wild animals because there they are well treated and safer from predators. However, and globally, the incidence of biocentric reasoning in the dilemmas is high, proving its increasing in situations in which human action is considered selfish or inappropriate, but it also is affected by the species presented (the empathy factor seems to be important as well). Implications of these results for Science and Environmental Education are also discussed.

Keywords: Children-animals relationship; Ecological dilemmas; Anthropocentric reasoning; Biocentric reasoning; Ecocentric reasoning

FRAMEWORK

The interest for environmental issues in the last decades conducted to the affirmation of the environmental ethics field, where different theoretical works in the way Human-Nature relationship is conceived can be found. In a simple categorisation, these works can be inserted in one of the following perspectives: (1) Anthropocentric – centred on an instrumental vision of nature and defending the sustainable use of earth resources. However, it can also emphasise the contribution of nature to the integral development of the human being in both physical and psychological terms; (2) Biocentric – centred on the intrinsic value of the other beings, with a strong opposition to multiple ways of their exploitation. Because it includes different approaches, it can be limited or confined to the more complex creatures (mammals and birds) or extend the moral consideration to all life forms; (3) Ecocentric – centred on the intrinsic value of ecosystems, whose equilibrium is more important than the particular interests of each species, including the human. It can also emphasise a deeper connection between humans and nature where aggressions towards nature are seen as aggressions towards our species.

In another context, environmental issues also entered the curricula of different countries, in association, specially, with Science Education and Environmental Education. However, in the case of Portugal, the dominant pragmatic view has conducted to the implementation of activities considered apparently neutral and consensual, not reflecting the rhetorical diversity found in the environmental ethics field, and only implicitly transmitting an anthropocentric perspective of nature (Cachapuz et al., 2002; Almeida, 2007). The excessive focus of teachers' environmental projects on resources management, drawing attention to simple actions like recycling, buying environment-friendly products, saving water or switching off the lights when one leaves a room or on the improvement of the quality of school areas can be explanations for this situation (Almeida & Vasconcelos, 2011).

RATIONALE

Beyond the field of environmental ethics, the domain of Developmental Psychology has also been interested in the incidence of anthropocentric and biocentric reasoning in children and adolescents. Studies by Kahn (1999, 2002) employed an interview methodology including questions about children's knowledge, beliefs and values related with environmental problems and applied it to three different regions of the world – Houston (USA), Amazon (Brazil) and Lisbon (Portugal). The results were very similar and revealed a low incidence of biocentric reasoning that tends to increase with age and can coexist, in some cases, with anthropocentric reasoning, reflecting a broadening of the mental organisational structure of the human-being. Kahn also found a type of biocentric reasoning, designated compositional reasoning that reflects a more holistic view of the environment because it is based on the integrity, beauty and sense of balance of nature. Compositional reasoning, a kind of ecocentric reasoning, clearly increases with age, especially in adolescence, and seems to depend on a deeper understanding of ecological concepts.

Trying to explain these results, Lourenço (2006) considered that the cognitive potentialities of reasoning not centred on the human beings are not being explored by school. But Kellert (2005) referred a new trend in the modern world, of which, in fact, we don´t know the exact implications: the direct experience in natural and semi-natural places is declining and being substituted by an indirect experience in places where nature is managed by the human-being, such as zoos, aquariums and other similar places. However, a different approach can be found in a study promoted by Kortemkamp & Moore (2009). They concluded that the incidence of biocentric reasoning can be related with the way questions are formulated. Children, when confronted with situations where human action is considered selfish or unfair, improved significantly this way of thinking.

In face of very different results, Almeida et al. (2011) promoted a study with urban children (ages 8 to 10), using an interview methodology, confronting them with one real and two hypothetical dilemmas involving animals, and also wanting to know the type of places where they had already met animals. The real dilemma was about the slaughtering of seals because they included codfish in their nourishment; the hypothetical ones were about the capture of a hedgehog and a small fox in the wild carried into a backyard in an urban environment. This type of questions generated high biocentric reasoning, even considering that the contact experience with animals occurs mainly in places where nature is managed. However, the fact that some children argued referring their empathy for seals, seeing them as friendly animals, and that, at the same time, some others referred the danger for humans of capturing a young fox (which are both anthropocentric arguments), conducted to the new/complementary study now presented.

Methods

To verify, once again, if biocentric reasoning is affected by the way of questioning but also by the animal species in presence, a new but similar questionnaire was built, with a few changes in the species presented in the dilemmas. Table 1 contains the questions used in the questionnaire and also their nature.

Table 1. Interview questions and their nature

Number	Question	Nature of the question
1	Can you tell me places where you have met animals in freedom?	Question about experiential aspects of the child
2	Can you tell me places where you have met animals in slavery?	Question about experiential aspects of the child
3	From all the mentioned places, which one did you like the most? Why?	Question about child's beliefs
4	From all the mentioned places, which one did offer the best conditions for animals? Why?	Question about child's beliefs
5	The amount of codfish in oceans is decreasing. Some scientists discovered that some shark species eat this fish. To prevent the continuous decreasing of codfish we are thinking in a way of killing a higher number of sharks. Do you think it is a right or a wrong decision? Why? If for you it is a wrong decision, what other measure would you take?	Ecological dilemma in relation to a real scenario
6	A family went for a walk in a forest and found a tortoise. One of the members caught it and brought it to their backyard. Do you think it was a right or a wrong decision? Why?.	Ecological dilemma in relation to a hypothetical scenario
7	A family went for a walk in a mountain and found a young wolf. One of the members caught it and brought it to their backyard. Do you think it was a right or a wrong decision? Why?	Ecological dilemma in relation to a hypothetical scenario

In this new questionnaire, the seal was substituted by the shark (a less friendly animal), the hedgehog by a tortoise (a less complex animal) and the young fox by a young wolf (a hypothetically more dangerous animal). The questionnaire was piloted first with 6 children and then applied to a sample of 91 children (ages between 8 and 10), attending the 3rd and the 4th years in a primary school of Lisbon, Portugal. It was a convenience sample, like the one in the previous study cited, improved by the authors, because it was formed by pupils of 5 teachers that usually collaborate with initial training courses for new primary teachers. All the questionnaires were applied by the same researcher in each class and started with the explanation of its purpose, knowing their opinion about certain issues, and emphasizing that there would be no right answers. Then, each question was read aloud by the researcher, and a time was given to each child to answer it; only after that, the next question would be proposed. We tried to avoid answers impossible to codify due a misunderstanding of the questions. The answers were codified as anthropocentric - if centred on any benefit for the human-being (children include); biocentric – if centred on the interest of other living beings, and ecocentric – if it appealed, even subtly, to holistic relationships between natural entities. We decided to include ecocentric reasoning, excluded in other studies, even knowing that probably it will have a small expression, considering that it depends on the comprehension of ecological concepts, which normally occurs in adolescence. Some examples of examples gave by the children were included not only for a better understanding of their codification but also to show the diversity of the ideas propose by the children. In the transcription of their answers, Seidman´s (1998) recommendation was followed, as he considers that, to preserve

the dignity of the participants of a study, some orthographic and semantic corrections must be included.
The percentage of each type of answer was compared with the one obtained in the previous study and in the presence of dissimilar results a chi-squared test (χ^2—non-parametric statistics) was used with a 0.01 level of significance to verify the homogeneity between the two samples.

RESULTS

The results confirm the lack of contact of urban children with natural and semi-natural places, with more expression in this study, considering the number of children that didn't remember seeing animals in the wild. Even so, the incidence of biocentric reasoning was still high but influenced by the focus of the questions, as answers to questions 3 and 4 are a good example. In the first one, when expressing their preference for places where they had seen animals, anthropocentric reasoning was dominant, with arguments about the quantity of animals seen, the fun they had, or emphasizing the fact they saw their favourite animal; in the second one, when invited to assess the animal conditions in the places referred, the tendency inverted and biocentric reasoning was almost exclusive, with considerations about the value of freedom, being in their habitat and having food, good treatment conditions or being protected from predators when in captivity, especially when zoos were referred. In fact, this last argument shows that for some children zoos conditions are even better than those in the wild, undervaluing the authenticity of the places as a criterion for animal welfare.
Considering the three dilemmas proposed, biocentric reasoning was again the most frequent as in the previous study. In the case of the shark dilemma, the highest number of the children criticized the killing of sharks. They didn´t agree for different reasons like the following: –They are killing a fantastic species‖; –...because they are living beings‖; –It is not fair to kill them and keep all the cod for us‖ or –...because all animals have the right to live‖. Some reasons even reveal, in some way, embryo ecocentric ideas: –sharks are important in nature‖ or –...because without sharks, cleaner fish don´t have any work to do‖. However, comparing with the first study where a seal was used in the dilemma instead of a shark, biocentric reasoning has less expression. The use of the chi-square test revealed statistically significant differences between the two samples ($p. < 0.01$), which proves the importance of the empathy factor in this type of reasoning. Even so, the majority of children that disagreed with the sharks slaughtering gave biocentric alternative solutions. Some examples: –I think that fishermen should fish less. In fact, they are not helping to deal with the situation‖; –We should not kill sharks and eat more vegetables and fruits instead, which is healthier‖ or –I propose to reduce cod fishing and then cod can reproduce and we can fish it again‖. Even so, a few creative anthropocentric solutions were suggested: –My solution would be to put sharks in a zoo‖ or –I think we should give them something to make sharks fall asleep and then fish the cod‖.
Considering now the two other dilemmas, the change from the hedgehog to the tortoise and from the young fox to the young wolf didn´t affect the biocentric incidence of the answers. In the first case, most children considered a wrong decision to catch the tortoise from the forest. Some arguments were: –...because the tortoise was at its natural habitat‖; –The tortoise will be sad because it doesn´t feel at home and in freedom‖ or –...because it will lose its family‖. Even those children that agreed with the action revealed they were worried with the animal welfare: –it was a good decision because a car or a truck could run over it‖ or –they did right because in a backyard there are many leaves for the tortoise to eat‖. In the second case, the arguments were similar but with a high incidence on the importance of keeping the young wolf with its parents/mother, when comparing with the tortoise dilemma. Some examples of the different reasons given by the children: –they did wrong because animals have the right to

be free‖; –it was a bad decision because the wolf is a baby and needs its mother´s cares‖; –they did wrong because young wolves must be near their parents and mountains are the place where they should live‖ or –...because wolves are wild animals‖. However, like in the dilemma with the young fox presented in the previous study, the danger factor had similar expression, emphasizing the problems to humans caused, for instance, by the growth of the young wolf‖. Some examples: –they did wrong because the wolf can attack when it grows up‖; –the wolf can kill someone and it bites‖ or –wolves kill people and eat chickens‖.

CONCLUSIONS AND IMPLICATIONS

The results of the two studies promoted show that the majority of children in the final years of primary school[1] can reason in a biocentric way and a few also reveal some perception of the holistic function of nature. That allows peers discussions to its promotion in those that can only argue in an anthropocentric way. Considering this, and other results presented, a systematisation of some implications for Science and Environmental Education is possible:

-To promote outdoor activities in very different places (natural e semi-natural).

It´s important to increase the diversity of places where children can contact with animals. Because their experience seems limited to places where nature is managed, like zoos and similar parks, the contact with natural parks and reserves is an important complement, especially because it promotes the fortuitous contact with animals, helping children to recognize that this type of experiences has a much higher value than the contact with animals in cages or small places where no effort is made to see them.

-To discuss, in particular, the zoos conditions, and those of similar places, for a better understanding of the relation between animal welfare and the authenticity of these places;

This recommendation is related with the previous one. It is also important that teachers explore zoos, not only in a scientific dimension but also in an ethical one.

-To diversify the issues in classroom, including some controversial ones that deal with human-animal-nature relationship, like sportive hunting, human-diet and species extinction, for instance.

In fact, because children can understand non-human centred arguments, the confrontation of different ideas and perspectives about these subjects can promote an important cognitive development of students and a better understanding of the cultural, social, economical and ethical dimensions that they include.

-To discuss pets, domestic and wild animals' specificities for a better understanding of the needs of each group;

It's important to explore the real needs of the animals from the groups mentioned above. In fact, some misconceptions were detected in the children´s ideas, and these may be related with the limited contact with places where nature is managed.

-To approach the ecological role of each species, independently from complexity, aesthetics and empathy, which can help to overcome the bad reputation of several animals due to superstitions or legends, often making them victims of irrational human behaviour.

Some children revealed some exaggerated perceptions about the real danger of some species, particularly those with a predatory instinct. Therefore, some work must be done towards a better understanding of the behaviour of these species, making their danger for humans more relative.

NOTES

1. Primary School in Portugal includes the first four years of Basic School. The ages of children are, normally, between 6 to 10.

FEEDING HABITS OF PRIMARY SCHOOL STUDENTS IN A RURAL AREA

Şenol BEŞOLUK[1] and İsmail ÖNDER[2]
[1]Sakarya University, Faculty of Education, Elementary Science Education, Turkey.
[2]Sakarya University, Faculty of Education, Secondary Science and Mathematics Education, Turkey.

Abstract: Skipping meal is important for the health and development of children and adolescents. This paper reports the findings of a survey of 162 elementary school students concerning the extent of skipping a meal. Results indicated that 21.6 % of the sample usually skipped a meal. The reasons indicated for skipping a meal was loss of appetite, lack of time, inadequate pocket money and to lose weight. Parents should be informed and educated about the feeding problems of the students and encouraged to provide meal to their children.

Keywords: nutrition, breakfast skipping, feeding habits, primary school, rural area

INTRODUCTION

Nutrition problems of the school children affects their physical and mental development, thereby affects their education. Nutrition problems can arise from various factors that can range from malnutrition to irregular and excessive feeding. Various factors such as socioeconomic, genetic, cultural, environmental, level of education about nutrition, and family affects students' nutrition quality and their habits. Underdeveloped, developing and developed countries even if the nutrition problems are of different sizes, face with Nutrition-related problems. One of those nutrition related problems is skipping a meal, especially the breakfast skipping. Breakfast skipping is highly prevalent in the United States and Europe (10% to 30%), depending on age group, population, and definition (Rampersaud, Pereira, Girard, Adams & Metzl, 2005). There are various factors of skipping the breakfast some of which are lack of time, diet, not being hungry in the morning (Shaw, 1998). According to Randler and Frech (2009) some of the students sleep late and they therefore find it difficult to get up in the morning, and they leave home without breakfast, but eat on the way to school, at school (Randler & Frech, 2009), or do not have at all. Therefore, breakfast skipping is an important problem associated with health and school functioning, because, without breakfast, school achievement and cognitive functioning may decrease (Shaw, 1998; Pollitt & Mathews, 1998). According to Randler and Frech (2009) breakfast skipping causes students to work at school with sub-optimal nutrition. They also have reported that in Germany there are few programs that give breakfast to students. Similar breakfast skipping and feeding problems have been reported in Turkey (Türk, Gürsoy & Ergin, 2007).

Evidence suggests that breakfast consumption may improve cognitive function related to memory, test grades, and school attendance (Rampersaud, Pereira, Girard, Adams & Metzl, 2005). Breakfast as part of a healthful diet and lifestyle can positively impact children's health and well-being. Parents should be encouraged to provide breakfast for their children or explore the availability of a school breakfast program. (Rampersaud et al, 2005). Hunger during school may prevent children benefit from education. Therefore, many countries, both developing and developed, have invested large sums of money in school feeding programs to improve attendance, achievement levels, and nutritional status, and sometimes to provide extra income for poor families by reducing the amount of money they spend on food (Powell, Walker, Chang & Grantham-McGregor, 1998).

Some studies indicated that skipping a meal is more common among children of lower income families. And few studies investigated why students skip meals. Therefore, the study was conducted on students with low socioeconomic backgrounds and their feeding habits, meal skipping reasons was investigated. For this purpose the following problems are investigated.

- Do students skip a meal?
- For what reasons students skip a meal?
- Do skipping a meal and the reasons for skipping a meal change with respect to some demographic variables (monthly income of the family, gender, and parents' occupation)?

METHOD

In this research feeding habits of students who came from low socioeconomic families was investigated. Therefore, purposive sampling methodology was followed. Purposive sampling methodology allows researcher to investigate information rich cases (Patton, 1990). Furthermore, in data collection survey method was used.

Sample

The sample of the study consists of 162 elementary school students. The age ranged from 12 to 15. Of the 162 students 78 were female and 84 were male. Monthly income of the families ranged from 250 to 750€. Most of the parents of the sample were primary school graduates (115 of the mothers and 116 of the fathers).

Data collection procedure

Informed written consent was obtained from the students' parents after permission had been obtained from the governorship. Parents were informed about the survey and explained that the responses would be confidential. Moreover, they had an opportunity to review the questionnaire. The researchers explained the study to all the students. Students completed the questionnaire anonymously.

Data collection instrument

A questionnaire was developed by researchers in order to obtain information regarding students' feeding habits. The first part of the questionnaire was composed of demographic questions and the second part was composed of questions that are written to examine students feeding habits. The questionnaire was composed of 21 questions. The questionnaire was investigated by three independent researchers for a validity study. These researchers indicated that the required information can be obtained by the prepared questions. Moreover, it was administered to a small group of students (N=12) before the study in order to observe whether there is any incoherent points.

RESULTS

Results of the study indicated that in total 21.6% of the students usually skip a meal (14.2% breakfast, 6.2% lunch, 1.2% dinner). Furthermore, 28.4 % of the students indicated that they occasionally skip breakfast, 43.8% skip lunch and 14.2% skip dinner. Students indicated several reasons for skipping a meal. The most common reasons they have indicated were "loss of appetite (56.2%)", "lack of time (9.2%)", "inadequate pocket money (8.0%)", " to lose weight (5.5%)", "nobody prepares a meal (2.5%)" and "unnecessary (2.5%)". The proportion of students who usually had their breakfast, lunch and dinner out was 17.3%, 27.2% and 1.9% respectively. Students generally eat fast food and pastry (bagel, pastry with meat or cheese filling, biscuits) and rarely do they eat dish of meat, and vegetable dishes while having their lunch. On the other hand situation is reversed for dinner. One sample chi-square test was conducted whether skipping a meal changes with respect to gender. The results of the test were not significant (Table 1); the proportion of male and female students that skips a meal was not different. Chi square test indicated that meal skipping depends on mothers' occupation. The follow up test indicated that meal skipping child proportion is higher for self employed mothers. The other follow up tests were not significant. Furthermore, meal skipping proportion was found to be related with father's occupation. The proportion of children who skip a meal was higher in families in which father is unemployed compared the others and the proportion was statistically higher than all others. The other follow up tests were not significant.

Table1. Demographic patterns of meal skipping

	Percent	(n)	Total	Chi-square
Meal skippers	21.6	35	162	
Gender				
Male	21.4	18	84	NS
Female	21.8	17	78	
Income				
250€ and lover	24.1	20	83	
251-375€	14.3	6	42	NS
376-500€	20.8	5	24	
501-750€	30.8	4	13	
Mother				
Home duties/not	22.5	29	129	
employed	16.6	5	30	P < .05
Laborer	33.3	1	3	
Self employment				
Father				
Laborer	20.2	19	94	
Self employment	17.5	7	40	P < .05
Government officer			1	
Retired	14.3	1	7	
Unemployed	40.0	8	20	

DISCUSSION

Meal skipping affects students' health, cognitive performance and physical and mental development (Rampersaud et al., 2005; Powell et al., 1998). Meal skipping is not only the problem of underdeveloped countries; it is also a problem for developing and developed countries (Powell et al., 1998). Especially breakfast skipping which is an important factor on cognitive functions, is common among students (Murata, 2000; Dwyer et al, 2001). In this study a considerable proportion (21.6%) of students was found to skip a meal usually and especially breakfast (14.2%). Furthermore, majority of students indicated that they occasionally skip a meal. The reasons given for skipping meal were almost exclusively loss of appetite, lack of time, inadequate pocket money and to lose weight. Results indicated that meal skipping and especially the breakfast skipping is an important problem for this sample (low socioeconomic level). Moreover, another problem is that the students generally consume fast food and pastry when they eat outside. These problems may result from several factors including inadequate sleep/sleep quality, socioeconomic problems, education level of the parents and their occupations. Meal skipping affects students in variety of ways therefore families and students should be informed about the effects of meal skipping and fast food consumption.

TEACHERS' UNDERSTANDING OF SUSTAINABLE DEVELOPMENT - DISCIPLINE BOUND DIFFERENCES

Carola Borg[1] and Niklas Gericke[1]
[1]Karlstad University, Sweden
Carola.Borg@kau.se , niklas.gericke@kau.se

Abstract: The purpose of this study was to investigate upper secondary school teachers' understanding of sustainable development (SD) and if their understanding differs depending on which subjects they teach. It is emphasized in the Swedish curriculum that SD is intended as a context for learning across the school curriculum and not only to be dealt with in certain subjects, and all teachers should teach according to a holistic perspective of SD. A holistic perspective integrates economic, ecological and social aspects. Since little is known about subject bound differences in teachers' understanding of SD we performed a nationwide questionnaire study among upper secondary school teachers (N= 3229), from 223 schools in Sweden. Pearson Chi-square test and Principal Component analysis was used to analyze the data. The result shows that differences in the way the concept is understood are linked to the subject taught. E.g. natural science and social science teachers think to a lesser extent that economic growth is important for SD compared to language, vocational and esthetical –practical teachers. There is also a difference of opinion regarding the social perspective and its inclusion in the concept. The ecological perspective is the perspective singled out by most teachers as integral to the concept. The results show incoherence in the way teachers understand SD, and it is not unlikely that they teach accordingly. The study points to the need for teacher education to provide a holistic understanding of SD including all perspectives. It is also important that in-service teachers are given further training.

Keywords: Sustainable development, Environmental education, Upper secondary school, Teachers understanding, Discipline bound differences.

THEORETICAL BACKGROUND AND RATIONALE

In 2005 United Nations launched a decade of education for sustainable development (SD), which address the impotence of education that empower people to develop attitudes, skills and knowledge to make informed decisions about, social, economic and ecological problems (UNESCO 2005). The Swedish curriculum states that SD should be integrated in all school subjects, and a holistic view of SD is intended to be the context for learning across the school curriculum, rather than only being addressed as an aspect of particular subjects (Swedish

National Agency for Education 2010). To fulfill these demands it requires that teachers, regardless of subject have appropriate knowledge and understanding of the complexity of the concept of SD. SD is a complex concept and several studies have shown that teachers have difficulties to understand the meaning of the concept. (e.g. Jucker 2002, Summers and Child 2007, Spiropulou et. al. 2007). Many teachers lack the necessary holistic perspective, which incorporate social, economic and environmental aspects (Spiropulou et. al. 2007, Summers & Child. 2007). A holistic view is seen as a necessity because social and economic factors often are the cause of environmental problems. To preserve the environment development is needed to meet humans' social and economic needs. Thus learning about economic, ecologic and social perspectives are intertwined and a prerequisite for each other in a holistic perspective of education for SD. Teachers lack of understanding could lead to difficulties when teaching according to a holistic perspective of education for SD because limited understanding of the subject often is related to limiting approaches to teach (Processer and Trigwell 1997). A holistic conception on the other hand has shown to lead to a broader approach to teaching and learning (Prosser and Trigwell 1997).

Many studies of teachers understanding of SD focus on geography or science student teachers' conceptions (e.g. Summers, Corney, and Childs 2004; Summers and Child 2007; Winter and Firth 2007) probably because these teachers traditionally taught environmental science and are looked upon as the predecessors expected also to teach SD. Little information exists on how education for SD is understood by teachers representing all subject areas, therefore further research is requested in other subjects (Corney and Reid 2007). This study presents the results from a nationwide survey in Sweden contributing to the comprehension of subject bound differences of upper secondary schools teachers understanding of SD.

PURPOSE AND RESEARCH QUESTION

The purpose of this study is to investigate teachers' understanding of SD and if this differs depending on which subject they teach.

Are there subject bound differences in upper secondary school teachers understanding of sustainable development?

METHODS

A stratified sampling of upper secondary schools (N=297) was conducted by the Central Bureau of statistics in Sweden (SCB), considering the size of the schools (three groups) and regions (four groups), to make sure that the sample was distributed on both small and large schools as well as different municipalities. Stratification by region provided a good geographic spread. 224 out of 297 schools (75 %) participated in our study and 3229 upper secondary teachers answered an online questionnaire with mostly liker-scale questions and some multiple choice questions. The questionnaire was first tested in a pilot study with 138 upper secondary teachers. Based on the pilot study minor modifications were made before the questionnaire was used in the main study. A large spread of teachers from different subject areas answered the questionnaire (over 20 disciplines were represented). 669 of the teachers were science teachers, 373 social science teachers, 483 language teachers, 713 vocational and esthetical-practical teachers, and teachers from remaining disciplines were 739. After the online questionnaire was closed the quantitative data was downloaded in SPSS version 18 for further data analysis. Persons Chi-square test was used to analyze relationships between variables, the significance accepted was $p<0.05$. Principal component analysis was used to analyze the relationship between how teachers responded in some questions.

RESULTS

Many (72%) teachers rate their personal understanding of SD as very good or good, but there was a difference between disciplines. Social science and science teachers rate their personal understanding of SD higher than the other subjects. 42% of the science teachers and 32% of the social science teachers report they have a very good understanding, compared to language teachers' (21%) and esthetical-practical/vocational study teachers (17%).

Subject bound differences in teachers understanding of SD was found in all tree perspectives (ecologic, economic and social) using PCA-analysis. The economic perspective of SD is the perspective of the greatest uncertainty, especially regarding the degree to which stable economic growth is a prerequisite for SD. Science and social science teachers look differently at the importance of economic development for SD compared to language and vocational and esthetical–practical teachers, see Figure 1. 10% of the science teachers and 14 % of the social science teachers agree that stable economic growth is a prerequisite for SD compared to 23 % of the language teachers and 25 % of the vocational and esthetical-practical teachers.

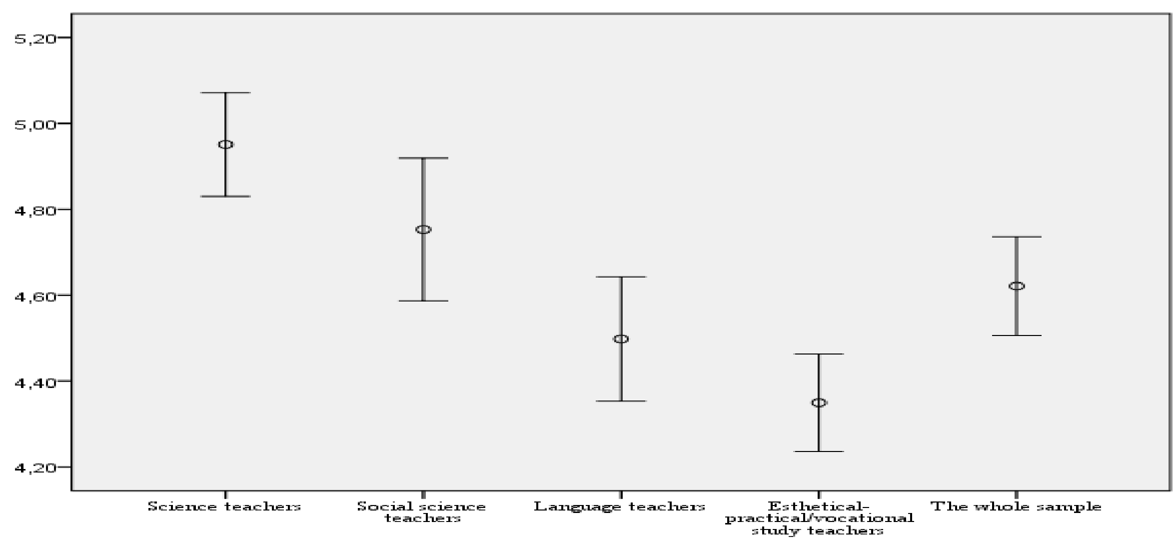

Figure 1. Indicator value (mean and 95% confidence interval) of the different teacher groups from the PCA-analysis about statements recognizing the economic perspective. The lower the number the more the teachers agreed the economic statements to be a prerequisite for sustainable development.

Our results showed that only about half of the teachers questioned considered social perspectives to be a component of SD. The social perspective was totally excluded from the understanding of sustainable development by 19 % of teachers and 29% only partially acknowledged its relevance. Results from PCA-analysis showed that language teachers, esthetical-practical and vocational study teachers in a higher degree recognizes the social perspective in the term SD than science and social science teachers.

The environmental perspective is the most recognized perspective of SD by all the teachers. Statements in the questionnaire that reflected the ecological environmental perspective received the strongest levels of agreement: *recycling waste products* (80 % completely agree), *developing new technologies to reduce the impact of harmful by-products of production* (72% completely agree) and *maintaining biodiversity in the local environment* (66% completely agree). However there were subject bound differences found using PCA- analysis, social science teachers recognize the environmental perspective in SD to a lower extent than language teachers and esthetical-practical and vocational study teachers did, see Figure 2.

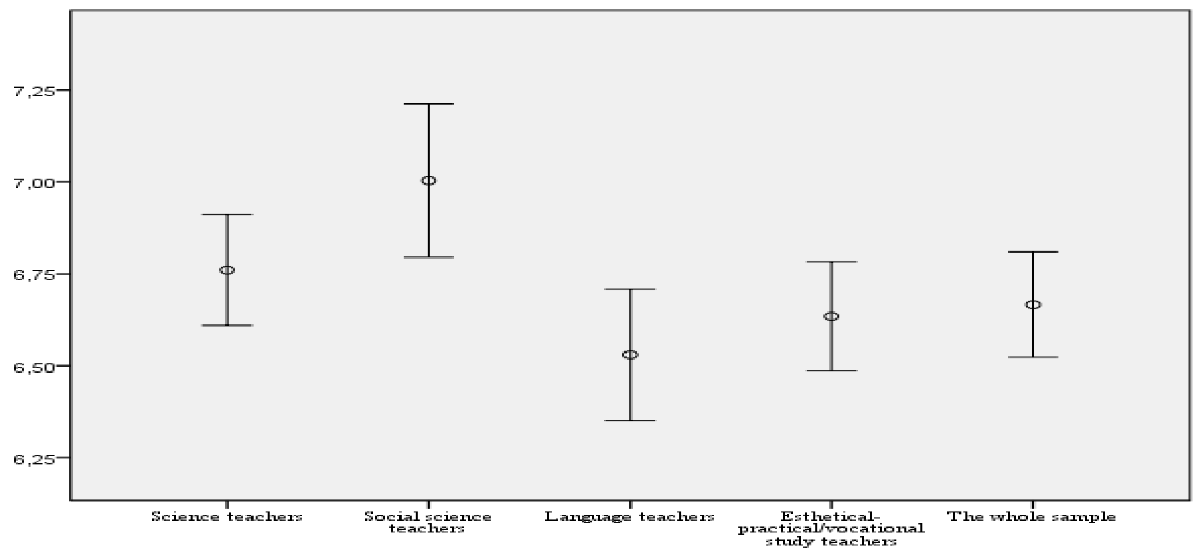

Figure 2. Indicator value (mean and 95% confidence interval) of the different teacher groups from the PCA-analysis relating to statements recognizing the ecological perspective. The lower the number the more the teachers agreed the ecological statements to be a prerequisite for SD.

Moreover we found that 76 % of the teachers had not studied SD as part of their teachers' education program and a majority (70%) reported that they had not received any further training of SD while working as teachers. A majority of the teachers want further training in SD (69%) but there were differences depending on discipline.

CONCLUSIONS AND IMPLICATIONS

This study shows that there is subject bound differences in teachers understanding of SD and it is not unlikely that they teach accordingly because limited understanding of the subject is often related to limiting approaches to teach (Processer and Trigwell 1997). The differences can be due to the fact that a majority of the teachers had not studied SD as part of their teachers' education program and had not received further training as in-service teachers. Therefore the teachers might build their conceptual understanding of SD on their own different subject traditions. This can be seen in the result of science and social science teachers, which emphasize ecological and social perspectives, respectively. Moreover social science and science teachers' had studied SD as part of their teachers' education programme to a higher extent compared to language teachers' and esthetical-practical/vocational study teachers. Surprisingly the civic teachers rated their understanding of SD as poorer than other teachers. The ecological aspect of SD is widely embraced by all the teachers in this study, which is in accordance with previous findings (e.g. Summers and Child 2007, Pepper and Wildy 2008). However the social science teachers recognized this perspective to a lower extent. The teachers' view of the economic perspective of SD is the perspective of the greatest variation among the different teachers, especially regarding the degree to which stable economic growth is a prerequisite for SD. This is also a highly debated issue in society depending on the interpretation of the concept of SD. However according to UNESCO (2005) stable economic growth should be integrated into a holistic view of SD. Science teachers and social science teachers seems more critical to this assumption, a result that could be interpreted as an imprint from the subject contexts of those teachers.

The influence of different subject traditions on individual's understanding of SD seems to be a general phenomena occurring at several different levels in the educational system. SD issues are marginal or even non-existent in some disciplines, but have a higher profile in others (Dawe, Jucker and Martin 2005). Most academic disciplines are limited by a set of disciplinary practices that constrain interdisciplinary efforts. Therefore, teachers are likely to build their understanding of SD on the foundation of their own subject traditions, as shown by the results presented herein. This could lead to problems in schools, in which sustainable development should be taught from a holistic perspective. In such a perspective interdisciplinary teaching is important for developing an understanding that nature and society constitute a holistic cluster of interdependent relationships according to Winter and Firth (2007). For teachers to work according to the Swedish curricula and the UNESCO guidelines this study points to the need for teacher education to provide a holistic understanding of SD including all perspectives. It is also important that in-service teachers are given further training about SD**.**

TEACHING ABOUT PLASTICS AND EDUCATION FOR SUSTAINABLE DEVELOPMENT IN CHEMISTRY EDUCATION

Mareike Burmeister[1] and Ingo Eilks[1]
[1]University of Bremen, Germany

Abstract: This paper discusses the development and evaluation of a lesson plan for chemistry teaching, which combines the overarching theme "plastics" with issues of sustainable development. It was designed for upper and lower secondary school chemistry classes in Germany, and employs the socio-critical and problem-oriented approach to chemistry and science teaching. Using the example of conventional and alternative polymer materials, pupils are taught basic content matter in the field of polymer materials, including the properties and structures of several important examples of plastics. However, this lesson plan also focuses on two directly related societal issues: the environmental pollution problem caused by plastic waste and the important question of achieving the sustainable production of goods for keeping prosperity. Therefore, a special teaching method was implemented, which mimics the work of consumer testing agencies. This method combines learning about how consumer test agencies actually carry out their work with reflective exercises, which look at the various dimensions of evaluating technical and societal developments from a sustainability perspective. These dimensions include economic, ecological and social impacts. The paper gives an overview of the lesson plan's theoretical background and its structure. Results from the accompanying research embedded in a project of Participatory Action Research, which is based on teachers' reflections and open and Likert-questionnaires from the students, will be presented. The results reveal that this approach provides a motivating and challenging framework for learning chemistry, including the aspects of sustainability and the often complex interplay between science, technology and society.

Keywords: chemistry education, curriculum development, plastics, Education for Sustainable Development, Participatory Action Research

BACKGROUND, FRAMEWORK AND PURPOSE

Taking the societal dimension of science more thoroughly into consideration in science classes has been an often repeated demand for modern science education (Hofstein, Eilks & Bybee, 2010). One of the most challenging societal issues faced by modern societies is the question of how to reap the benefits of science and technology, while nevertheless protecting the environment and responsibly stewarding potential resources for the benefit of future generations. The juggling act of balancing current prosperity with the well-being of future generations has been subsumed under the banner of sustainable development and should of necessity be taken up by science education. After the Brundtland-Report was released, national policy-makers acknowledged that education has a key role to play in sustainable development. Education has a responsibility to turn out future citizens who are able to act in responsibly in society and, therefore, promote the concept of sustainable development (UNCED, 1992). Because of this, the UN declared the years 2005-2014 to be the Decade of Education for Sustainable Development (DESD), a period which was intended to integrate the principles, values, and practices of sustainable development into every aspect of education (UNESCO, 2007).

Within the overarching DESD structure, Education for Sustainable Development (ESD) has been operationalized in various ways, since every nation has its own plan of action. In Germany, for example, De Haan (2006) suggested a set of competencies which pupils should acquire in order to shape our society in a sustainable fashion. According to De Haan, such competencies encompass capabilities including communication, evaluation, and personal action in society. The didactic approach selected in this instance is in line with Bybee's (1997) concept of multidimensional scientific literacy as the major goal of any sort of science education. This also neatly ties in with Activity Theory-based science education and the German concept of *Allgemeinbildung*, or "general education" (Hofstein, Eilks & Bybee, 2010). Many other models show similarities with the German concept. They all focus on interdisciplinary learning, innovative methodology and the integration of societal, economic, and ecological aspects into science learning (e.g. Paden, 2000; McKeown, 2002, 2006)

Chemistry education faces a very special challenge within this framework (Burmeister, Rauch & Eilks, under review), because chemistry represents one of the core disciplines contributing to sustainable development in any industrialized society (Bradley, 2005). Innovative products and more efficient production methods lowering both waste and energy consumption would not be possible without modern chemistry research and development programs or without the widespread application of the principles of Green Chemistry in both research and production. Yet, even though chemistry plays a key role in sustainable development, the networking and dissemination of teaching materials focusing the learner's attention on sustainability issues beyond a purely technological perspective in chemistry classes typically remains a phenomenon of individual efforts in fits and starts. An organized, widespread team effort remains lacking in most countries and educational systems. In Germany, teaching practices that explicitly approach and expand upon ESD in chemistry education under recognition of economic, ecological and societal impacts remains the exception rather than the rule (Burmeister & Eilks, 2011a). Thus, our project aims at developing and researching new chemistry lesson plans and teaching materials in order to explicitly include ESD issues in German teaching. This paper presents a lesson plan on plastics, which combines the learning of basic chemistry with reflections on the implications this substance's use and production may have in the field of sustainable development.

METHOD

The research and development of this lesson plan was based on the Participatory Action Research (PAR) model for science education by Eilks and Ralle (2002). In PAR, teachers and researchers jointly develop and investigate teaching practices. PAR combines the evidence from educational research with the practical experience of in-service teachers as two complementary resources in their own right for the improvement of teaching practices. A group of teachers and researchers cooperatively design, test, research, and refine the lesson plans in a cyclical process. The output of this model includes new concepts and materials for teaching, an enlarged knowledge base of research on teaching and learning, improved practice, better trained teachers, and documentation of authentic teaching practices (Figure 1). The accompanying research collects evidence covering teachers' and students' perceptions of the lesson plan and its effects using a multi-perspective approach.

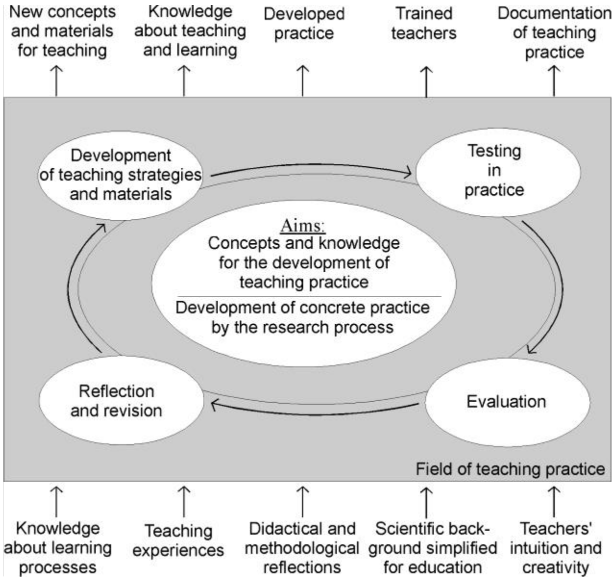

Figure 1. The model of Participatory Action Research in science education (Eilks & Ralle, 2002)

In our case, a team of 10 teachers from different schools (Markic & Eilks, 2011) worked on the design of a lesson plan for plastics, which included learning about the aspects of sustainable development. For roughly one year, the lesson plan was structured and repeatedly re-negotiated in monthly meetings of the action research group. Accompanying this process, several testing phases took place. After the changes had been adapted into the chemistry subject matter included in lesson plans, the lessons were tested in five different classes ranging from grade 9-13 (age range 15-19). Data was collected from both teacher reflections and discussions occurring during the regular meetings of the action research group. An open questionnaire covered students' reflections on: 1) what they considered to be the most important things they had learned, 2) their personal opinions about the lesson plan, and 3) what they now believed about the different types of plastics. Additionally, a Likert-questionnaire was filled out by the pupils, asking for their opinions of the lesson plan. Questions were subdivided into three parts, asking whether the students had liked the topic, how they would rate the methods employed, and if they had experienced a change in their personal attitudes towards the issues of sustainability, consumer tests and plastics.

LESSON PLAN

The lesson plan follows the 5-step model of the socio-critical, problem-oriented approach to chemistry teaching (Fig. 2) as described by Marks & Eilks (2009).

In phase 1, the lesson plan starts with a textual approach based on excerpts from authentic, controversial magazine reports covering the use of conventional plastics and comparing them with emerging environmental problems. The students are assigned different aspects taken from the texts, which are handled in the lesson plans. The material is structured in manner that provokes both questions about the basic chemistry of polymer materials and inquiries into their value with an eye towards the ecological, economical and societal perspectives.

Concept of the socio-critical and problem-oriented approach to chemistry teaching

Objectives	Criteria for selecting issues and approaches	Methods	Structure of the lesson plans
Allgemeinbildung/ education through science	Authenticity	Authentic media	1. Textual approach and problem analysis
(Multidimensional) Scientific Literacy	Relevance	Student oriented chemistry learning and lab-work	2. Clarifiying the chemistry background in a lab environment
Promotion of evaluation skills	Evaluation undetermined in a socio-scientific respect	Learner centred instruction and cooperative learning	3. Resuming the socio-scientific dimension
Promotion of communication skills	Allows for open discussion	Methods structuring controversial debating	4. Discussing and evaluating different points of view
Learning science	Deals with questions from chemistry and technology	Methods provoking the explication of individual opinions	5. Meta-reflection

Figure 2. Model of the socio-critical, problem-oriented approach to Chemistry teaching (Marks & Eilks, 2009)

In phase 2, students learn the basic chemistry content behind the various kinds of plastics with the help of a learning-at-stations lab exercise (Eilks, 2002). Each station covers different aspects of the production of plastics, the various properties and structures of polymers, differences between plastics and other materials such as wood or metal, and the nomenclature of important polymer materials.

Phase 3 resumes the societal debate and introduces students to a simple concept of sustainability. After reconsidering the initial question of how to evaluate different plastics (and their use) with respect to ecological, economic and social implications, phase 4 of the lesson plan, which is structured around the consumer test method (Burmeister & Eilks, 2011b), begins. The consumer test method as an application of the idea of mimicking authentic social practices (Eilks, Marks & Burmeister, 2011), in this case the practice product testing as performed by consumer testing agencies. In this phase, the learners compare different kinds of plastics: polyvinylchloride (PVC), polyethylene terephthalate (PET), and thermoplastic starches (TPS). Each of these plastics has individual advantages and disadvantages. The use of PVC is widely disputed in society, mainly because of certain plasticizers which are used in its production and the problem of an environmental friendly recycling and deposition. On the other side PVC is very stable, has fantastic properties and can be easily and quite cheaply produced. In contrast, PET is viewed in public debate quite neutrally. Nevertheless, there is debate because of serious environmental and social problems associated with the recycling process if PET waste is exported to countries with low social and environmental standards. TPS as a biodegradable polymer usually enjoys very positive populist reviews. But TPS is still expensive and has an extremely limited potential for widespread application. So all the plastics have advantages and disadvantages which in a holistic evaluation will counter interact.

M2 Evaluation Sheet

Plastics Evaluation criteria	My weighting factor	weighting factor of the group	Weighting factor of the class	my assessment	assessment of the expert group	assessment of the mixed group		
Plastic						PVC	TPS	PET
Green Chemistry	%	%	%					
Production and use without dangers for humans and environment								
No problems for disposal or recycling								
Production primarily from renewable resources								
Low energy costs for production								
Consumer and social interests	%	%	%					
Production, use and reuse take place according to West European social standards								
Safe usage for humans and animals also in the case of improper use (burning, swallowing, etc.)								
Products available cheaply everywhere								
Economy and industry	%	%	%					
Industrial production possible without subsidies								
Good marketability								
Recycling possible								
Material characteristics	%	%	%					
Good durability and long lifespan								
Good material properties and a broad area of usage								
Decision			100%					
Decision from the entire class								

Evaluation key:
++ = very good (1) + = good (2) o = satisfactory (3)
⊖ = barely sufficient (4) – = unsatisfactory (5)

Figure 3. Evaluation sheet for the consumer test method

Pupils work on the different kinds of plastic within a jigsaw puzzle classroom structure. They learn about the various advantages and disadvantages of each sort of material. A worksheet familiarizes the learners with the different perspectives such an evaluation can encompass. These range from the economic aspects of production to availability and consumer friendliness issues to ecological concerns about production processes and waste removal in the context of 'Green Chemistry'. It also asks them to weight the importance of the different dimensions. Stepwise following the Think-Pair-Share method the students have to negotiate a weighting between the different dimensions of a potential evaluation, namely properties, ecological, economic and social impacts. Then the students evaluate the pros and cons of their specific sort of plastic. The class is divided into small groups with at least three members each for this purpose. Each group covers one of the three types of plastics. The groups are asked to weigh these arguments against one other and evaluate the sort of plastic. Students work individually on their particular plastic first, assigning individual marks for each category, which will be discussed in their group later on. Beginning with their individual decisions, the students present and discuss their personal considerations and are forced to reach a compromise with their experts group. Following the jigsaw classroom method, the groups are mixed then together in such a manner that at least one expert for each type of plastic is in the new group. The newly-formed groups thoroughly discuss and evaluate all the type of plastic in comparison. The pupils' groups then jointly fill out an evaluation sheet (Fig.3). By the end of this process, each group now has completed the entire evaluation sheet and the final marks can be calculated, first within the individual groups of the second round of the jigsaw classroom, then for the entire class.

The processes of weighting and evaluating are reflected upon in the final phase. At the heart of the reflection stand the questions of how such evaluations occur and how they are influenced by the individual decisions of the people conducting the test and/or writing the reports. This reflection focuses on the role of scientific information and its constant transformation and filtering in the process of evaluation, but also touches upon the reliability of information sources and the transformative process, which occurs whenever members of consumer testing agencies use, relate and weight information in the sense of “filtered information” (Eilks et al., 2011). Another point which is discussed is the marks assigned to the products. Students are asked if they had initially expected the marks to turn out differently and why this was so. Another interesting discussion point is that individual marks generally differ from the end decision reached by the entire class. This makes clear the above-mentioned influence and importance of individual weighting and personal interests and contrasts them with consensus-based, group decision-making processes, where compromise on an issue is unavoidable (Eilks et al., 2011).

FINDINGS

Judging by the teachers’ reports, this lesson plan proved to be both highly feasible and motivating for their learners. The students were highly involved in both inquiry activities and cooperative learning processes right from the start. For example, the question of how to evaluate different sorts of consumer products was an unfamiliar and challenging one for most of the participants, students and teachers. Many pupils had some difficulty in the areas of assigning their own weighting factors and in reaching joint agreements. This phase incited intense discussions about the different sorts of plastics. More importantly, it provoked debate about the role the various evaluation dimensions should have in categorizing a product like plastics. For example, the durability and affordable prices associated with PVC ran headlong into this plastic’s poisonous nature if burned under uncontrolled conditions and its environmentally persistent nature if not handled through sustainable recycling. The excellent degradability of TPS was contrasted with its high production cost and limited applicability. Such contradictions led to productive confusion and intense reflection upon the evaluation process itself. In the end, it was also interesting to see that the different opinions in all the learning groups were flattened to an average value, with no extreme positions being represented by the final outcome. Each type of plastic was found to be neither very good, nor very bad. This was not what the pupils had expected to see, as they bluntly stated in the open questionnaire. Even some of the teachers mentioned that they had never really intensely reflected upon consumer testing activities in such an intense fashion.

Most pupils agreed on the questionnaire that they considered the lesson plan to be very useful for their future lives. About 65% totally (30% partially) agreed that they now felt able to cope with consumer test reports released to the public. Roughly 75% totally (20% partially) agreed that the lesson plan had made them think more thoroughly about the use plastics. Approximately 65% (20% partially) agreed that they had changed their opinion about plastics. Among the different learning groups, younger pupils tended to more fully agree to most of the statements on the questionnaire. Older students sometimes said that they had already been critical about the use of plastics. Nevertheless, even among the older students a majority agreed that the learners had become more critical towards consumer testing results and/or the use of plastics. Especially the older participants mentioned that learning about plastics and consumer tests was useful and relevant for their lives. With respect to ESD, over 80% of the pupils agreed that they now better understood what the discussion about sustainable development is really about. An overview of all the results is given below (Fig. 4).

Many students recognized in the open questionnaire that it is possible in chemistry education to learn more than just chemistry subject matter. They did consider the learning in chemistry within this lesson plan to be relevant for their lives. For example, students mentioned to have gained knowledge about sustainability and the way consumer tests are devised and carried out. Some explicitly mentioned that they had become more critical towards consumer tests and what they had to offer. Only a few pupils offered criticism of the teaching unit. A few replies to the questionnaire said that the lessons had not included enough chemical reactions and formulae, and that participants had had to discuss things too much. A feeling was expressed that this type of lesson is not really "chemistry", but would better fit into the social sciences. This observation reveals an interesting insight into the perception of chemistry held by these pupils. Discussing controversial issues and evaluating chemical content does not seem to belong to their definition of chemistry class (e.g. Marks & Eilks, 2010). In their opinion, such things are not considered to be a reasonable requirement of chemistry teaching and learning. It appears that the conventional teaching approaches experienced by these pupils up to this point have given the learners only an abbreviated, distorted picture of what chemistry really is. But these were only a few students. Overall, the questionnaire delivered very positive feedback, which is the case for the results from both the open questions and the Likert-test items.

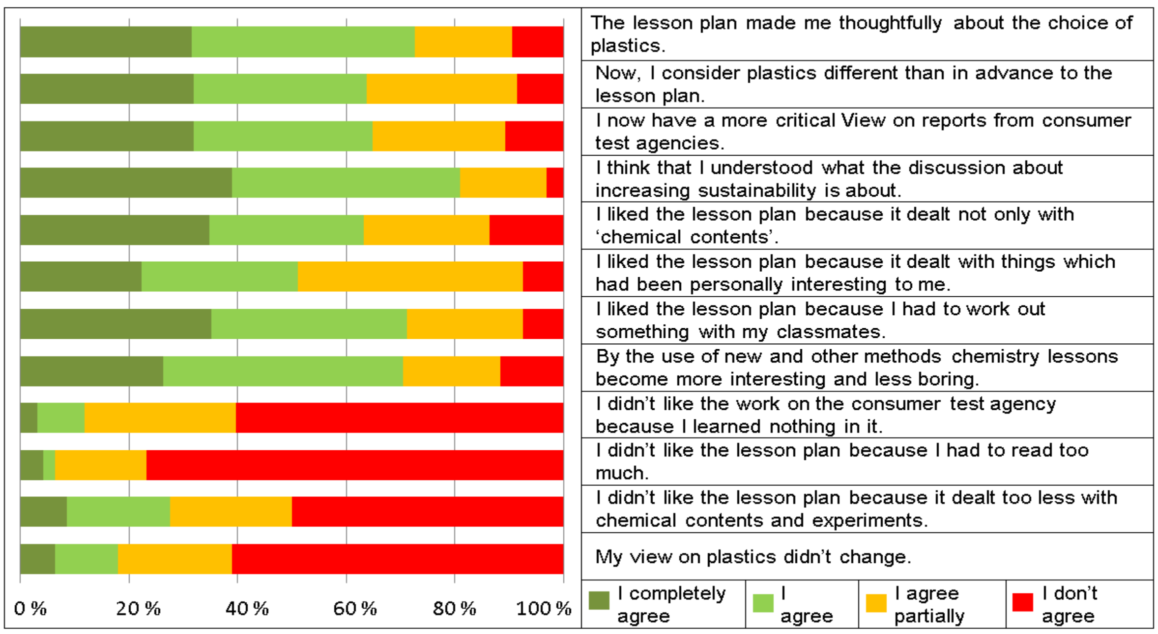

Figure 4: Results of the Likert-questionnaire

CONCLUSIONS

Using Participatory Action Research as a starting point, this project was able to cyclically refine the teaching materials developed, aided by feedback from the teachers and students alike. Although there were some initial problems caused by the complexity of the method, solid results could be reached during the evaluation. In the final analysis, this lesson plan on plastics and their broader implications for sustainable development proved to be a very highly motivating addition to the ESD-geared curriculum and pedagogy being developed for German chemistry lessons. This was especially successful thanks to the inclusion of the consumer test method (Burmeister & Eilks, 2011b), which added an authentic, societally-relevant and controversial facet to the learning process. This is supported by the responses of both the students and their teachers.

Like previous examples of such teaching units (e.g. Marks & Eilks, 2010) have demonstrated, the socio-critical and problem-oriented approach to chemistry teaching (Marks & Eilks, 2009) has shown itself to be a very feasible platform for undertaking such lesson planning. The case study presented here reveals that this approach can provide very fertile ground fruitful for integrating important aspects of ESD more thoroughly into everyday chemistry teaching, including the use of more explicit and multidimensional methodologies in this process, at least in the case of Germany. As the ensuing evaluations showed, students can become increasingly contemplative with respect to both their environment and the decisions they make concerning sustainability and available resources. This is an encouraging and very useful step when it comes to creating a modern, sustainable society of responsible stewards, who do not lose sight of future generations and the problems they may face.

HOW STUDENT TEACHERS FORM THEIR EDUCATIONAL PRACTICE IN RELATION TO SUSTAINABLE DEVELOPMENT

Ingela Bursjöö[1]

[1]University of Gothenburg, Department of Physics

ingela.bursjoo@physics.gu.se

Abstract: This study investigates experienced student teachers' perceptions of their professional training to encompass education for sustainable development, ESD. Data were collected by using questionnaires. The findings indicate that teachers' implementation of ESD depends on both external and internal factors. Three major external factors have been found: colleagues, time and the curriculum. The internal factors were identified as transformative phases; especially a disorienting dilemma, self-examination, exploration of options for new actions, acquisition of knowledge and skills, and integration of new action in the teaching of ESD. Tensions between the individual teacher as a professional versus the teacher as a private person are explicitly mentioned as well as tensions with other teachers, principals and the community. These results may be important to teacher education as well as teachers' professional development as they provide insights for implementation of changes in the educational system.

Keywords: education for sustainable development, educational change, transformative learning, external factors, internal factors, student teachers, disorienting dilemma.

Education for change needs change in education

ESD has been described in the Swedish curriculum since 1994 as a "learning to illustrate how society functions and the way we live and work are best adapted to create sustainable development" (National Agency for Education, 1994). However, the degree to which teachers are prepared to work with these issues varies with the consequence that ESD cannot yet be considered satisfactory implemented in all schools (National Agency for Education, 2009).

Working with education in a changing social and policy context is demanding and the descriptions of education for sustainable development are still blurred. The widely accepted definition of ESD from the WCED (1987) "Sustainable development is to be able to meet the needs of the present without compromising the ability of future generations to meet their needs" is both vague and open to interpretations (Wals, 2006). Analysis of the concept "education for sustainable development" shows that it differs from environmental education and is more than a new name for the same content. Teachers thus need to change their teaching. This change is not only about new knowledge – but perhaps involves even changing the frames of reference for how to understand the world. That implies a teacher role and a teacher identity that might mean a transformation for the teacher. The theories of transformative learning offer an analytical tool for such research.

Transformative learning

Transformative learning is described as a process in which individuals alter the frames of reference in terms of understanding the world in order to make them more comprehensive and perceptive. Jack Mezirow (2000) describes ten stages of a transformative process:

(a) A disorienting dilemma; it shows when the learner describes some kind of tension or dissatisfaction with the situation, that could also be recognized as a trigger event for the transformation.

(b) Self-examination; becoming critically reflective of the premise of the problem

(c) A critical assessment of assumptions

(d) Recognition that your discontent and the process of transformation are shared with others; there is a connection between your discontent and the process of transformation

(e) Exploration of options for new roles and actions, relationships and action

(f) Planning a course of action

(g) Acquisition of knowledge and skills for implementing your plan

(h) Provisional trying of new roles

(i) Building of competence and self-confidence in new roles and relationships

(j) A reintegration into your life on the basis of conditions dictated by your new perspective

Critical self-reflection is thus necessary to bring about a change of frames of reference, a potential change of perspective. This approach to learning focuses particularly on values, ideals, and emotions, moral as well as abstract concepts such as liberty, justice, responsibility and democracy. Moore (2005) furthermore stresses that

> I believe sustainability education must be interdisciplinary, collaborative, experiential, and potentially transformative. Sustainability education is also a process of creating a space for inquiry, dialogue, reflection, and action about the concept and goals of sustainability.
>
> Moore, p. 78

Teacher identity research has found that professional identity has a major impact on the way teachers teach and their ability to cope with changes in the educational system (Nias, 1989).

Rationale and research questions

Teacher education is a powerful arena for educational change and the student teachers are potential change agents who soon will be heading out into school as teachers. Thus, these experienced student teachers near graduation are an interesting group to study. Three research questions guide the study:

1. What external factors are described by the student teachers as barriers in their teaching of ESD?

2. What internal factors – analyzed in terms of the phases in the transformative learning - can be identified in the student teachers reflections about their relation to education for sustainable development?
3. What tensions, dilemmas and conflicts are described by the student teachers?

The methodology and interpretation of the statements in this study is informed by a qualitative categorization (Cohen et al, 2007) where the qualitative data analysis involves making sense of patterns, themes, regularities and categories. The empirical design uses questionnaires. This collection of written data provides relatively short and reflected answers compared to oral interviews. All student teachers answered the following questions:

1. If you got unlimited resources, then how would you educate for sustainable development?

2. What barriers can you see in order to achieve your goals explained in the previous question?

The sample in this study consists of 20 student teachers, with diverse subjects in their degrees. The age range of the respondents in this study is from 24 to 55 years, with a total of 20 student teachers, 6 male and 14 female. Data were collected using questionnaires during a compulsory course in education for sustainable development and all of them answered the questions.

In this study two analytical tools are operationalized to fit the structure of the results. Firstly, Hargreaves (2004) distinction between external and internal factors is used in the analysis. These external and internal factors are used to analyse whether these student teachers refer to something external that affect their action, such as politicians, policy documents, pupils, community, colleagues, or if they describe more internal processes. Secondly the internal factors are compared to the transformative phases and interpreted in order to discern similarities or differences.

Results

The answers express how the student teachers discern certain external factors such as time, colleagues and the curriculum that impact their action. The student teachers also express knowledge about the writings in the curriculum regarding sustainability. The responses show descriptions of an educational system that is perceived to be slow in its process of change. It also appears that the student teachers are unsure of the exact nature of the requirements that the school has on the teachers related to ESD and what is expected beyond the more traditional environmental perspective “recycling and paperless classroom”. The content in ESD is described by the respondents as focusing on particular issues such as environment, consumption, health, democracy, energy, justice, resources and economy. The answers also describe the teaching methods as collaborative and interdisciplinary; ESD requires individual skills as well as a collective competence.

Internal factors-the different phases of transformative learning

The different perceptions held by the student teachers are described thematically and then compared to the transformational phases and some excerpts of the typical statements are represented in this table. The internal factors were interpreted as they correspond to the transformative phases although the sentences often are difficult to precisely put in just one of the transformative phases. None of the answers suggest that the current situation is satisfying. When one of the student teacher says ”… we are destroying our world ” it is in the same answer described that she talks about human rights, environment as well as working conditions, that everything is connected, social perspectives as well as the environment. The self-examination (phase *b*) is a reflective mode when individuals look at their own situation. The competence in the field of sustainability issues – or rather lack of competence – is emphasized in several statements, for instance as described in "… that my knowledge in the field isn´t large enough could also be a barrier". Sometimes personal shortcomings – such as laziness or shortage of time – are expressed in the answers, for instance "No, I don´t always practice what I preach, but I´m aware of it and try to do something about it. Because of comfort, laziness and tiredness I prioritize other things…" Many answers talk about that it is important what other people do, for instance "Sustainable development demands cooperation, work interdisciplinary, work in teams".

Overall, many alternative actions are described in the answers (phase *d*) in order to change teaching methods; to cooperate with the surrounding community, field trips, but also to welcome other professionals to school. No teacher student in this study is without suggestions for actions. Some of the answers show that it is work in progress "…sustainable development has a price, I try to live as lean as possible but I haven´t acted in every way yet".

The exploration of options for new roles (phase *e*) can apply to the teacher as an individual as well as a professional and these different roles are often intertwined in the answers. Some explorations are described not only for the individual's own action but for a collective action as well: "Send all teachers and principals together on professional development". The provisional trying (phase *f*) and the planning of a course of action (phase *g*) are sometimes difficult to discern from each other in the answers, on teaching practice the student teachers have opportunities to both plan and try out new actions, such as "we plan a project about consumption, all teachers will cooperate about this for three weeks".

The student teachers also address several of the economical, ecological and social dimensions of sustainability (phase *h*). The statements show that this group of student teachers describes interdisciplinary cooperation as important, tradition-breaking and unusual. Many of the student teachers describe that they want to work interdisciplinary and wish they would experience that in their professional training. The building of self-confidence in new roles (phase *i*) – which is an issue of identity, is described typically as "It's about working on issues that do not have simple answers, this requires a humble teacher's role, sustainable development also requires collaboration". Thus, openness to the surrounding world, engagement and non-prestige are characteristics that these student teachers express and are typical of the professional role related to education for sustainable development. Some of the student teachers describe the acquisition of a competence that involves a change in attitude towards the teacher's control of learning. The signs of reintegration in your life (phase *j*) are recognized in different ways such as the student teacher highlights a thumb rule for how to act, for instance "to set a good example and practice what you preach, above all, never do the opposite of your values“. Signs of courage – in not always having the correct answers – could be seen as expressed in “I do not always know the answer, but must have the courage to address things that are not entirely clear. Teachers have to be self-critical”. The teacher role in education for sustainable development is described as “the role of the teacher seems to be quite fuzzy, some teachers, at some schools, seem to have come a long way, others have barely begun to reflect on sustainable development”. The description of the integration of the new action is also depending on external factors such as colleagues, time, resources, leadership, policy documents and other incentives, which complicates the process of change for the teacher.

Described conflicts of interest in ESD

Conflicts between various interests are described in the answers when the student teacher interact with teachers, management, policy documents, time, pupils, financial resources and their own lifestyles. Overall, an image is emerging in this study of student teachers who want to cooperate with others, allowing themselves not to know the answers to everything, who do not use an explicit norm about how society ought to be. This teacher identity seems to have a strong personal commitment, often self-critical and work with existential issues. However, between the lines a different picture emerges: other teachers who do not cooperate, who guard their own subject, not engaged in content or students, not reflecting on their teaching role, not changing their educational practice. These two poles: the individual self and the other lead to friction in the interaction, a tension between the individual and the environment.

Three tensions could be identified; either between the student teacher as having a professional role versus a more private role as well as tensions with other people (described as teachers and principals) and the educational system. The student teachers put high demands on their own lifestyle, both as a professional with great insight into human needs and a strong character. Some of them express shame or guilt that they, as private persons, are unable to live by their ideals related to sustainability issues such as sustainable transport, sustainable consumption and sustainable energy. Other responses also describe how the teacher is expected to “teach how things fit together”. It is described as a high trustworthiness to act on your speech; this also seems to be perceived as something new and challenging in the teacher role. Significantly the student teachers describe it as central to collaborate with colleagues when working with ESD.

Discussion

The motivation to educate for sustainable development is strongly expressed for these respondents but they experience many barriers for the implementation of ESD, external as well as internal. The research question regarding the internal factors related to education for sustainable development has been compared to the different phases of transformative learning. According to the transformative learning theory the student teachers will undergo a process of change only if they are dissatisfied with the way they perceive the current situation. All these external and internal factors put the student teachers into dilemmas and conflicts when reflecting over their teacher identity. Their dealing with these conflicts, tensions, dilemmas, arguments and disagreements are described in the answers. This implies a teacher identity that is different from transmission of facts or norms. The difficulty to identify a common framework of understanding what education for sustainable development could mean contributes to the difficulty the student teachers say they perceive. Anxiety for not being good enough as a teacher can lead to many things; both dropouts from the profession, illness or even turning towards a cynical approach to the profession. These possible consequences need to be addressed, as noted by Hargreaves (2004). If we can understand the change process that these experienced student teachers undergo, it could lead to better teacher education and professional development for teachers.

DEVELOPMENT OF COMPETENCES AND CONDITIONS FOR GOOD PRACTICES IN ESD. A QUALITATIVE INTERNATIONAL SURVEY

Silvia Caravita[1] *and Pierre Clément*[2]
[1]CNR Roma (Italy), silvia.caravita@istc.cnr.it
[2]S2HEP, University Lyon 1, Université de Lyon (France), Pierre.Clement@univ-lyon1.fr

Abstract: The concept of competence is still controversial. An operational definition in the educational field considers competence « *holistic in the sense that it integrates and relates external demands, individual attributes (including ethics and values) and context as essential elements of competent performance".* Each competence emerges from the interaction among « *knowledge (including tacit knowledge), motivation, capacities, attitudes, values, emotions, mobilized for effective actions in particular contexts ».*

Our qualitative analysis identified competencies expected by projects of Education for Sustainable Development and the conditions for their development. Reports about "good practices" of UNESCO associated schools and an inventory of case studies in Italian Secondary Schools have been analysed to highlight the five learning pillars (to know, to do, to be, to live together and to transform) pursued by these experiences. The specific competencies were matched with a list of ESD themes, and with phases of realization of projects aimed at producing some change in the close life-environment.

The development of the teachers' competencies seems to largely occur in parallel with the actualization of the experiences; teachers' and students' motivation appear mutually contagious and certainly play an important role.

The integration of disciplinary knowledge in real life problems, and the identification of unifying trans-disciplinary conceptual networks, need attention.

Keywords: Education for Sustainable Development – Competencies – School practices

THEORETICAL BACKGROUND

The concept of competence is still controversial and even more so, its application in the real curriculum is far from being consistent with its potential innovative drive, as highlighted by the opinions and experiences expressed by the participants from 46 countries in the E-Forum on Approaches by Competencies (2006).

Conceptual and procedural knowledge were viewed as separate and independent cognitive competences in the solution of problems before being inter-related in a model of development in which either one or the other may develop first and influence the other depending on the experiences offered by the context to the learners (Sophian, 1997). "Conceptual knowledge may guide their attention to relevant features of the problem and help them to organize their information in their representation of the problems. This well-chosen problem representation may then support generation and use of effective procedures” (Rittle-Johnson and Siegler, 2001)

The initial tendency in cognitive sciences was to discriminate among ways of defining competencies which focused on cognition or performance or on knowledge domain (specific or general). The DeSeCo project achieved a consensus on an operational definition of competence in the educational field: « *holistic in the sense that it integrates and relates external demands, individual attributes (including ethics and values) and context as essential elements of competent performance”.* Each competence emerges from the interaction among cognitive and practical abilities : « *knowledge (including tacit knowledge), motivation, capacities, attitudes, values, emotions, mobilized for effective actions in particular contexts* ». In addition to cognitive competencies, competence-related motivation plays a very important role.

The *competent handling of a situation* constitutes the principal criterion for evaluating situated competence (Jonnaert et al., 2006). Therefore, in a competency-based curriculum, exit profiles specify the classes of situations that learners must be able to handle competently by the end of their education.

RESEARCH QUESTIONS

The design of ESD strategies promoted by UNESCO is based on the integration among three dimensions: environmental, social and economical situated in cultural contexts, and on a constructivist perspective about teaching/learning that aims at developing learning to know, to do, to be, to live together, to transform

The relevance of this interaction among knowledge, values and attitudes and practices is widely acknowledged by the educational systems as the fertile humus for the growth of competencies, but countries have specific priorities concerning the expected competencies. Many of the competencies envisaged for ESD correspond to the key-competences for education: act autonomously, use physical and socio-cultural tools (symbolic languages among them) for effectively interacting with life-environment, with others in heterogeneous groups, for participating as active citizen. But other competencies are strictly linked with the objectives and pedagogical approach of ESD that makes multi-disciplinarity, systemic and critical thinking the core of its actions.

Our research wants to explore which kinds of students’ and teachers’ competencies are potentially developed by the ESD projects in the actual school practice. To which extent are they specific of cultural contexts? Which are the features of the projects and the conditions in which they are enacted that teachers assumed to be effective for the growth of competencies? Can they be assessed? Which recommendations might be generalized for the diffusion of ESD ad also the transfer of its strategies to other areas of curricular teaching?

METHODS

Our study is a bottom up investigation carried out through a qualitative analysis of reports about ESD projects. We have concentrated on Secondary School projects and given priority to the variety of themes treated. Our sources of information are:

- UNESCO selections of “good ESD practices” that collect the reports written by the teachers following a predefined grid. The projects belong to five regional areas

(Africa, Arabian area, Asia and Pacific area, Europe and North America, Latin American and Caribbean area)

- Inventories of case studies in the Italian Secondary Education collected by direct contacts with the coordinators of the projects.

The reports for each school project have been analysed by filling up a table as the one inserted below (most of the work was done in French).

Competencies (KVP, inside a cultural context) K = Scientific Knowledge, V = Values, P = Practices					
Theme and location. Declared objectives Disciplines involved Promoters of the project Collaborating agencies	**« To know » (connaissances, démarches, valeurs)**	**« To be » (valeurs, attitudes, motivations)**	**« To do » (pratiques, savoir-faire, valeurs)**	**« To live together » (valeurs, pratiques, connaissances)**	**« To change » (soi-même, les autres, l'environnement)**

Twenty projects have been presently analysed. Ten Italian ESD experiences have been identified and the teachers who coordinate these projects have been interviewed to highlight their conceptions of competencies and of the positive and negative factors influencing the ESD activities in schools. The analysis of these interviews is still in progress.

Our formulation of the competencies that the students have possibly built has to be considered as an a-posteriori emergent construct, because it synthesizes the information contained in the table and the description of the pedagogical approach of the project.

The competencies have been clustered by ESD themes to highlght the aspects that were privileged; they have also been organized within a framework that links the competencies to different modalities of students' participation in the projects.

PRELIMINARY RESULTS

The examined projects document the great creativity and dynamism of the engaged teachers and schools. The development of the teachers' competencies seems to largely occur in parallel with the actualization of this kind of experiences because teachers' and students' motivation appear mutually contagious and certainly play an important role.

Actions aimed at introducing changes in the local environment, in making the school a point of reference and a resource for the community, make the goals of most of the experiences. The challenges faced by these goals, individually and collectively accepted, are at the origin of the high motivation: there are no pre-existing answers to the questions, everyone is intellectually and operatively engaged.

It is interesting to underline that the reports of the projects rarely use the term of competence to specify either what is envisaged either which were the results attained by the learning processes. We considered the competencies as the eventual integration of the five kinds of learning that were more or less explicitly indicated in the reports.

We reproduce here an example from our report for the UNESCO (Clément and Caravita, 2011, p. 65):

Table N°11, Accademia de Averroes Peace Programme, Pakistan

Context: Communities where students experience the consequences of cultural and religious prejudices

Knowledge: knowledge about cultures and religions of the social groups composing the community; awareness of the interconnections among discrimination, economic deprivation and social marginalization; understanding the interdependence between environmental and human health

Cognitive abilities: ability to give meaning to cultural diversities, ability to search for relationships among socio-economic, cultural and environmental dimensions in contexts, critical thinking; ability to de-contextualize and generalize problems

Practical abilities: abilities for establishing positive social relationships with different members of the community, skills for cooperating in actions of social solidarity, communication skills

Attitudes: curiosity, openness, trust

Emotions: empathy, appreciation, satisfaction, self-esteem, self-confidence

Values and ethics: responsibility, valuing diversity, pursuing the ideal of justice

Motivations: willingness to share with others, interest in diversities, motivation to go beyond the surface of facts, availability to be involved in concrete social actions and policies

Competencies: competence to make explicit the prejudices that undermine the cohesion of local society (racism, integralism, injustice, …); higher awareness of the factors which require a responsible engagement at the individual and social level to contribute to build a more sustainable future; capacity to communicate, to understand and to cooperate with other members of the community with open-mindedness and appreciation for diversity; better understanding of the interdependence between ways of living and environmental quality.

We found clear evidence that the competencies are cued by and coherent with the context itself, its demands, the situations/problems which are identified or which are created by the pedagogical approach. Therefore to formulate the competencies in general terms seems to erase the many important variations that distinguish the school class experiences among them when engaged in similar projects (without mentioning the individual differences). Listing standard ESD competences might result in a sterile exercise, even if it appears necessary for orienting the design and assessment of projects.

The activities planned by the teachers are finalised to "problems for sustainability and search for solutions " but the projects may involve the students in different phases of this process, therefore the contribution of the types of learning in building the competencies may differ. The students can mainly have the role of *participants* in "models" of action, or of *designers* of possible solutions, or of *actors* in the operational translation of projects. We therefore framed the competencies in categories (Clément and Caravita, 2011) that may help to reflect on how knowledge, abilities and values can be implicated in different ways.

One critical point in teachers' mediation, in fact, seems to be how to regulate the interaction among these components consistently with the purposes of the ESD project, how to capitalize on motivation and emotions as magnifiers of cognition. The integration of disciplinary knowledge in real life problems, the identification of unifying trans-disciplinary networks are issues which demand for greater attention in teachers' education and in the curricula.

Abstract: The environmental, social and economical dimensions of ESD include human rights as equality of all the human beings independently to their gender, ethnic group, religion or sexual orientation. To analyse teachers' conceptions on environment and on human rights, and to identify eventual links between them and with controlled parameters, a large survey has been done in 24 countries (8 749 teachers). The data are submitted to multivariate analyses.

In the less developed countries, the teachers' conceptions are more anthropocentric, less awareness of the problem of the limit of resources in our planet, and less reticent to use GMO (genetically modified organisms). These teachers are more believing in God, more practising religion, more for *"a strong central power", "against the separation between science and religion"*. The priority of ESD in these countries is poverty and development, while it is to avoid wasting and excessive consumption in the most developed countries.

The teachers with the most anthropocentric conceptions more agree with these propositions: *"It is for biological reasons that women more often than men take care of housekeeping*" and "*Ethnic groups are genetically different and that is why some are superior to others*", and more disagree with: "*Homosexual couples should have the same rights as heterosexual couples"*. These points illustrate that some socio-cultural traditions can differ from values of ESD (the universal human rights).

Keywords: Environment – Teachers - Values – Gender – Human Rights –

THEORETICAL BACKGROUND

Most of the countries include now ESD (Education for a Sustainable Development) in their national curricula, even if some of them still call it EE (Environmental Education, e.g. in Brazil or in Colombia, where EE already included social, economical and political dimensions), or EES (Environmental Education for Sustainability, e.g. in Australia) avoiding the word "*Development"* more understood as "*Growth*" than as a possible "*Metamorphosis*" of our societies. The topics of ESD are far to be limited to ecology or environmental problems; they also include the social and economical dimensions of SD (Sustainable Development, Brundtland report 1987), including human rights.

ESD is focused on learners' competences. « *The conceptualization adopted in DeSeCo (OECD 2002) is holistic in the sense that it integrated and related external demands, individual attributes (including ethics and values) and context as essential elements of competent performance"* (Rychen, 2004, page 21). In each competence, *"knowledge (including tacit knowledge), motivation, capacities, attitudes, values, emotions,* (are) *mobilized for effective actions in particular contexts* » (Rychen, 2004, page 22).

The values underlying ESD were categorized in diverse works (synthesis in Caravita *et al.* 2008). Several of these values are also underlying Education for All, Education to Citizenship and Human Rights : e.g. for the equality of all the human beings independently to their gender, ethnic group, religion or sexual orientation (UNESCO, 2009, page 9). Other values, more focused on Environment and Sustainability, are specific to ESD.

ESD is facing a paradoxical injunction, taking into account the local socio-cultural specificities, but also universal values (mainly scientific and citizenship values). To face this question, we did an international survey implying different socio-cultural contexts. Our research is trying to identify eventual interactions between scientific knowledge and values in teachers' conceptions (as suggested by the KVP model: Clément 2006, analysing conceptions as possible interactions between scientific knowledge, K, values, V and social practices, P), and the present communication is focused on the analysis of eventual correlations between values related to environment and those related to some human rights.

RESEARCH QUESTION

What are the teachers' conceptions, and mainly their values implied in competencies for ESD, in a variety of different countries? More precisely, is there some correlation between their values related to environment (as ecocentric or anthropocentric ethics) and their values related to some human rights as equality among all the human beings, independently to their gender, ethnic group, sexual orientation, or religion?

METHODS

The teachers' conceptions were analysed from their anonymous answers to a large questionnaire elaborated by the Biohead-Citizen project (Biology, Health and Environmental Education for better Citizenship, 2004-2008), elaborated and validated collectively during two years, using previous interviews, pilot test, etc (Clément & Carvalho 2007). 27 questions are related to nature, environment and environmental education, other questions are dealing with the eventual biological justification of differences related to the gender, to ethnic groups or to sexual orientation; other questions concern personal information, including political and religious opinions. We present here only some results of the survey.

In each country, the sampling was well balanced: 1/3 primary schools teachers; 1/3 secondary schools teachers of biology; and 1/3 secondary schools teachers of language. In each sample, there were half of in-service teachers, and half of pre-service teachers (end of their training). The countries were chosen from their diversity: 18 for the Biohead-Citizen project (13 in all Europe, 4 in Arabic countries and 1 in sub-Saharan Africa). More recently, were added 2 other European countries (Denmark and Serbia), 2 countries of sub-Saharan Africa (Burkina-Faso and Cameroun), Brazil and Australia. The number of the interviewed teachers in each of the 24 countries is indicated below on the figures 1 and 2 (total = 8 749).

The distribution of answers inside each of the 24 countries can be illustrated by histograms as below in figures 1 and 2. The data were analysed with different multivariate analyses (presented in other works as in Munoz *et al.*, 2009). A between analysis was used to identify the answers which discriminate the most the countries, and a test of randomisation (Monte Carlo type) shows that the difference among the countries is very significant ($p < 0.0001$). A Co-Inertia analysis correlates the PCA from the questions related to environment with the PCA from questions related to the teachers' socio-political and religious opinions. Another Co-Inertia Analysis correlates the environmental variables with those related to some human rights (equality men – women, among ethnic groups, etc.).

MAIN RESULTS AND DISCUSSION

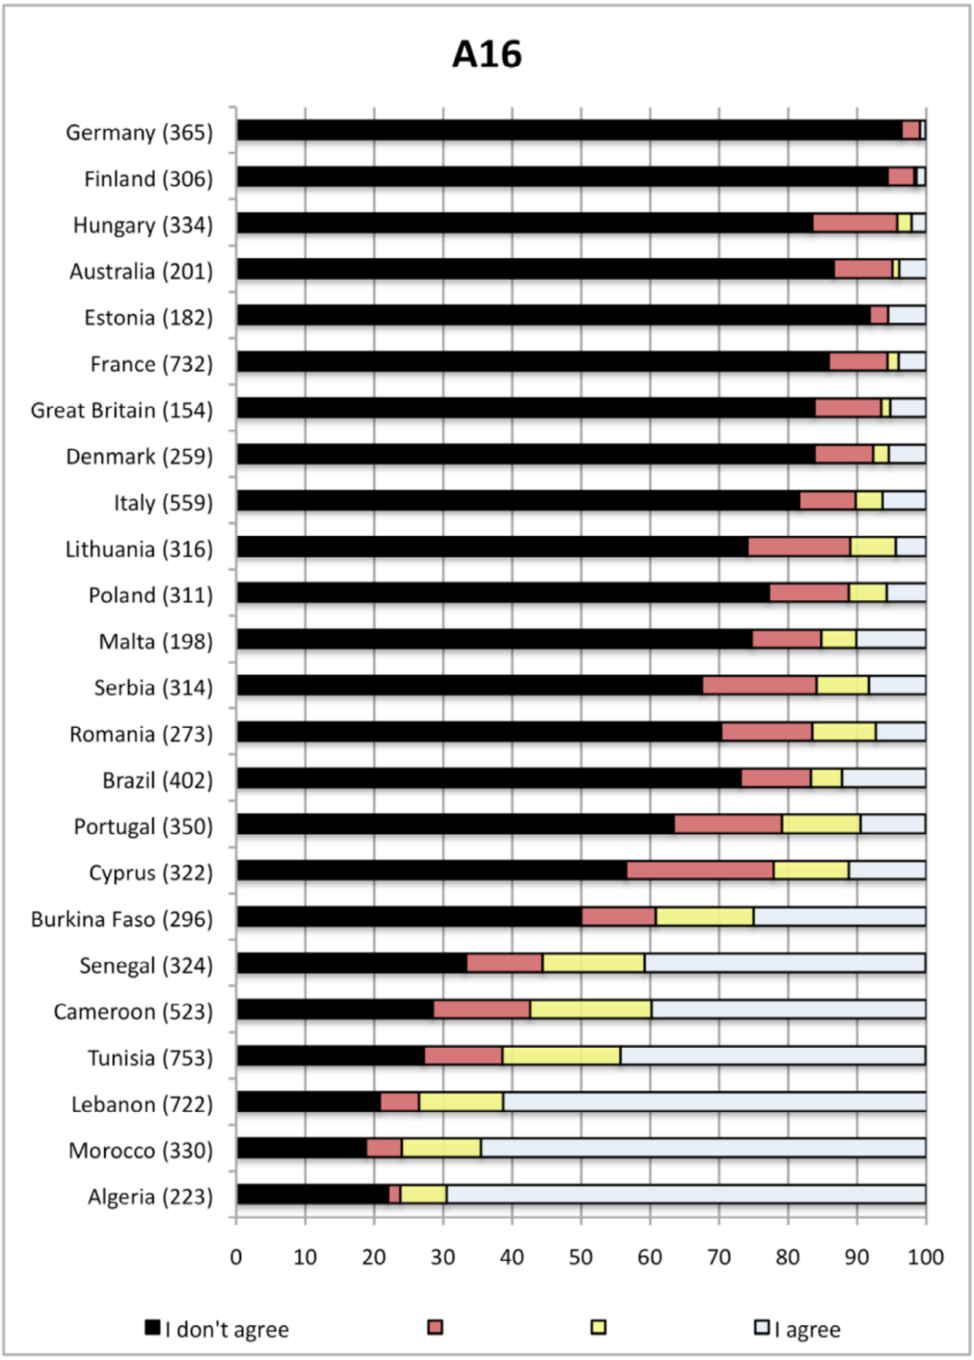

Figure 1 – Answers of the 8 749 teachers (grouped by country) to the questions **A16 - *"Our planet has unlimited natural resources"***

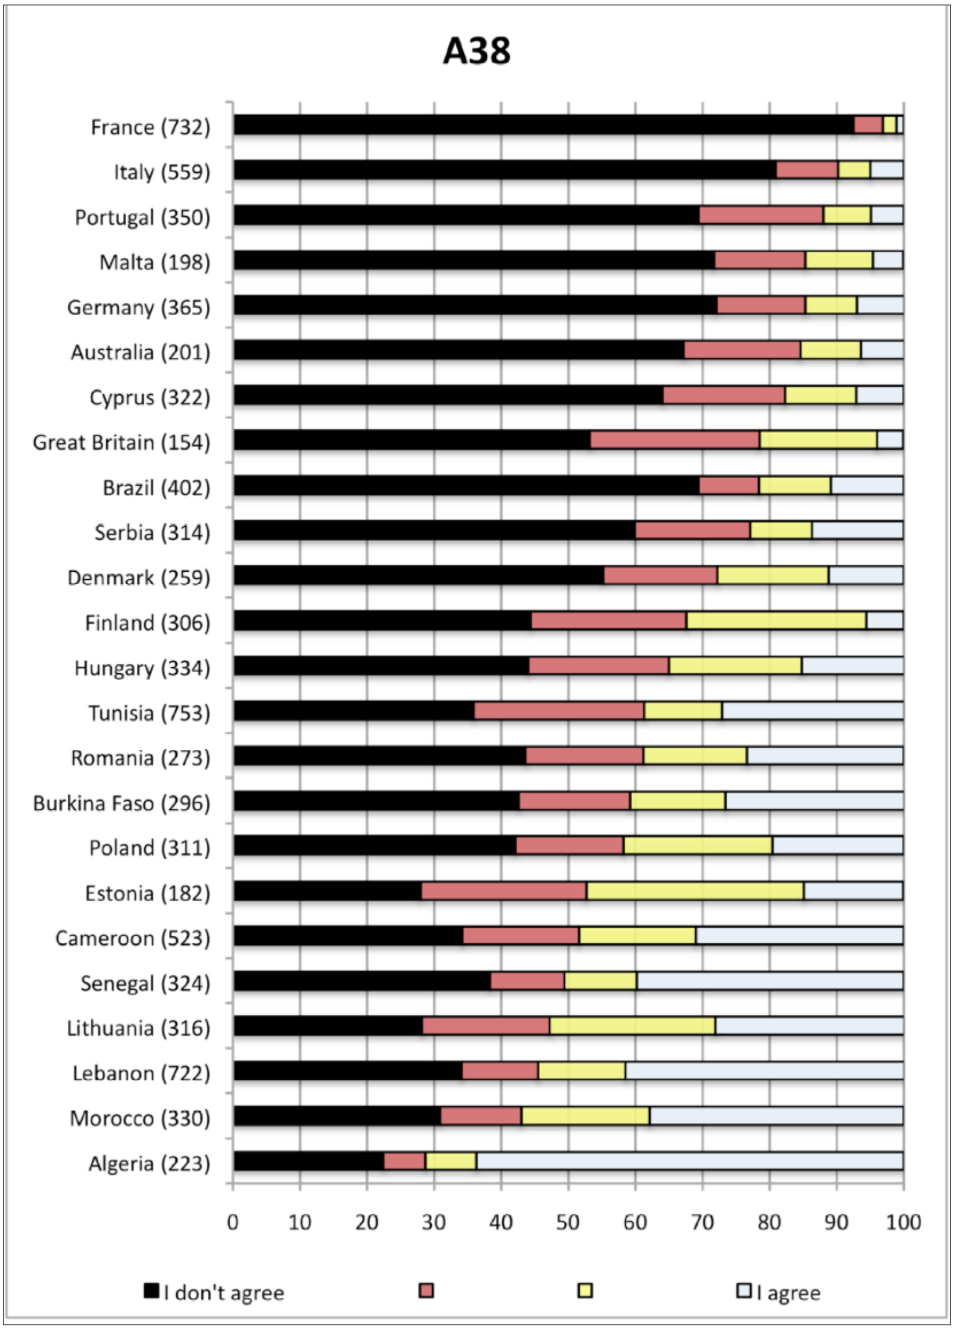

Figure 2 – Answers of the 8 749 teachers (grouped by country) to the question **A38 –** ***"It is for biological reasons that women more often than men take care of housekeeping"***

The 24 countries very significantly differ from several questions related to teachers' conceptions on utilisation of the environment (Several questions concerning teachers'conceptions on utilization of the environment make the difference mong the 24 countries:): as questions A16 (figure 1: *"Our planet has unlimited natural resources"),* A17 *("Society will continue to solve even the biggest environmental problems"),* A18 *("Human beings are more important than other living beings")*, A39 *("Genetically modified plants are good for the environment because their cultivation will reduce the use of chemical pesticides (e.g. insecticides, herbicides)").*

Globally, teachers of the less developed countries have more anthropocentric conceptions, being less awareness than their colleagues from other countries of the problem of the limit of resources in our planet, and less reticent to use GMO (genetically modified organisms). These conceptions probably can be related with the importance of poverty in these countries, and the urgent necessity of a better economical development. The implementation of ESD in these countries has to take into account this specificity, not using the same situations as in developed countries where inverse problems are a priority (to avoid wasting and excessive consumption).

The first Co-Inertia Analysis shows a significant correlation between the same environmental variables (anthropocentric values) and some religious and socio-political parameters. The teachers having the most anthropocentric conceptions are the most believing in God and practicing religion, independently to the religion (e.g. in figure 1, A16 : most of the teachers in Cameroon are Christian, while >90% of them are Muslim in Senegal). Politically, these teachers are more for *“a strong central power”, “against the separation between science and religion”,* and for *“laws to help firms”.* All these parameters are probably linked to the low level of development correlated with stronger religious practices.

The second Co-Inertia Analysis shows another set of correlations. The teachers with the most anthropocentric conceptions more agree, for instance, with the propositions A38 (figure 2: *“It is for biological reasons that women more often than men take care of housekeeping*”) and A35 (“*Ethnic groups are genetically different and that is why some are superior to others*”), and more disagree with A41 (“*Homosexual couples should have the same rights as heterosexual couples”*). The biological justification of superiority of men or of some ethnic groups is today considered as ideological and not scientific; as an interaction KV (knowledge and values) justifying some still actual social practices (P). Why is it so present in teachers’ conceptions in Arabic countries, but also in sub-Saharan Africa, and in countries of North and East Europe? These points, as other comments of the figures 1 and 2, and of all our results, will be presented and discussed in a larger publication. They illustrate that some socio-cultural traditions can differ from some values of ESD (the universal human rights).

THE TURKISH ADAPTATION OF THE ENVIRONMENTAL EDUCATION AND ECOLOGICAL BEHAVIOR QUESTIONNAIRE

Nilgün DEMİRCİ[1], *Funda ERASLAN*[1], *Sema YILDIZ*[1]
[1] Middle East Technical University, Faculty of Education, Secondary Science and Mathematics Education Department Ankara/TURKEY

Abstract: The purpose of this study was to create an instrument to measure environmental attitude and ecological behavior of pre-service science teachers in order to investigate the predictive power of environmental attitude and knowledge in relation to ecological behavior. Hence, this research includes adaptation of an environmental attitude and ecological behavior questionnaire (EAEBQ) into Turkish and reports validity and reliability of the study. Adapted instrument developed by Kaiser, Wölfing and Fuhler, (1999) is a likert type instrument with five scales and includes 26 items. The sample was 108 university students from two universities in Turkey. The data collected from two universities was analyzed and the Cronbach's alpha reliability was found to be 0.710. Environmental education and ecological behavior are the core of the most commonly used attitude approaches toward the environment and all these concepts forms the conceptual skeleton of the planned behavior. Then, this study draws attention to the role of the education and the faculty of education to improve our understanding of the ecological behavior.

Keywords: Science education, environmental education, environmental attitude adaptation, pre-service teacher education.

Background, Framework, and Purpose

Environmental issues are increasingly taking more attention of the entire world for last decades. Especially after the 1970s environmental problems have been accounted as their social dimensions as well as technical and economical dimensions. With the awareness of environmental issues' social and economic dimensions and modified knowledge about environment, our perspective in terms of gained environmental knowledge, attitudes and behavior have been changed (Digby, 2010). Starting with assumptions that the environment is in danger and must be saved, some environmental problems and solutions are propounded.

From this perspective The UN Conference on the Human Environment in Stockholm, Sweden in 1972 is important as it was the first conference about environment and environmental problems (UNEP, 1972). Then, the Belgrade Charter conference of educators at Belgrade, Yugoslavia, in 1975 developed a framework of understandings for the field. The other important intergovernmental conference was Tbilisi Declaration in Russia, in 1977. In this conference declared goals, objectives, criteria and principles for the field (www.nzaee.org.nz). The World Commission on Environment and Development in 1987 entitled as "Our common Future"(Brundtland, 1987) is the other most important report that emphasize the importance solutions for environmental problems in terms of social and economic dimensions. These conference and reports make this clear that environmental problems are social problems, caused by the behavior of people and it is crucial that how to “educate” people to become "part of the solution" by taking action to save sustainability.

Environmental education (EE) is developing new behaviors not only at the individual level, but also at society. EE emphasizes development of scientific knowledge and appropriate solutions for environmental problems. Moreover, environmental educators and researchers have long been interested in knowledge about and attitudes toward environment since it was assumed that knowledge and attitudes significantly influence environmental behaviors (Coyle, 2005; Kollmuss & Agyeman, 2002; Koupal & Krasny, 2003; Smith, Rechenberg, Cruey, Magness & Sandman, 1997; as cited in Kaiser, Wölfing, Fuhler, 1999).

Environmental attitude is also considered one of the most promising concepts (Newhouse, 1990). Almost % 70 of all environmental psychological publications cover environmental attitude (Kaiser, Wölfing & Fuhler, 1999). Many studies indicate that if people have high level of environmental concern they should be more likely to engage ecological behavior (Roberts, 1991; as cited in Roberts & Bacon, 1997). Also, so many researchers thought that poor attitude-behavior correspondence is a result of inappropriate attitudinal specificity (Roberts & Bacon, 1997). Hines, Hungerford, and Tomera (1987) concluded that there was a positive moderate relationship between environmental attitudes and behavior (Hines, Hungerford & Tomera, 1987). Roberts and Bacon (1997) also stated that who have highly environmental concern, choose products that create less pollution and try to make ecologically correct decisions about products.

Based on the related literature stated above research questions of this study were determined as follows:

1. Is Environmental Attitude and Ecological Behavior Questionnaire (EAEBQ) reliable to use into Turkish culture to assess pre-service science teachers’ environmental attitude and ecological behavior?

Rationale

Although there are some studies about environmental attitude, some of which are conducted with adults, consumers and different levels of students. There are limited studies about pre-service secondary education science teachers’ environmental attitude, knowledge and behavior in Turkey. Also, most of studies in the literature do not use environmental attitude as a predictor of ecological behavior, still as researches indicated that there is a gap in research done in the area of relationship between environmental attitude and behavior in university students (Kaiser, Wölfing, Fuhler, 1999). Also the original environmental questionnaire includes all these three aspects. For this reason, this study have importance to fulfill this gap especially for Turkey by considering the predictive power of environmental attitude and knowledge in relation to ecological behavior at pre-service science teachers, and to measure the relationship between ecological behavior and environmental attitude of pre-service teachers from different departments.

Moreover, requirement of environmental education in universities is the most prominent issue in nowadays (Moody et. Al., 2005; CELP, 2005; Kaplovitz & Levine, 2005). Because, after graduation from university, one is expected to reflect his learned environmental value, attitude and behaviors his surroundings. Therefore, the goal of the universities should be facilitate to have knowledge and positive attitudes about environmental issues and develop new behaviors towards the environment. So, determine of university student’s environmental attitudes and then measure the relationship between attitude and behavior are the crucial in the environmental education. This study have importance to fulfill this gap especially for Turkey by considering the predictive power of environmental attitude in relation to ecological behavior at pre-service science teachers, and to measure the relationship between ecological behavior and environmental attitude of pre-service teachers from different departments.

Methods

The original Environmental Education and Ecological Behavior Questionnaire (EAEBQ) consists of 28 items on a 5-point Likert-type scale. The response categories were “absolutely disagree”, “disagree”, “undecided”, “agree”, and “absolutely agree”. The subscales of questionnaire are Environment Knowledge (EK) and Environmental Values (EV) and Ecological Behavior Intention (EBI).

In this study, EAEBQ was adapted by researchers by the way of one-way translation. First, the EAEBQ was translated from English to Turkish by two of researchers. Addition to researchers, one more independent bilingual researcher translated the original questionnaire into Turkish, allowing divergent interpretation of items with ambiguous meaning in the original questionnaire. The Turkish form of the EAEBQ was checked over by one environmental education expert in terms of appropriateness of the items in order to check the face and content validity. According to the feedbacks, some items were found to be inappropriate for Turkish culture and items 14 and item 16 were dropped out from the study. Finally, EAEBQ revised and final form of the questionnaire was produced. The adapted instrument is a Likert-type instrument with five scales, includes 26 items and it was applied to 108 pre-service science teachers (48 physics teachers, and 60 chemistry teachers).

Results

The data were collected from pre-service science teachers and analyzed via PASW for Windows. Pre-service science teachers’ responses were tallied according to their response (for example; absolutely disagree =1 or absolutely agree =5). Negatively formulated items were reversed in coding. The maximum score is 130 and the minimum score is 26. The reliability of the EAEBQ was analyzed as Cronbach’s alpha value and found as .710 for the total test. For educational studies, the suggested alpha value is at least .70 and preferably higher (Fraenkel & Wallen, 2003, pp.168). Also reliability analysis of subscales of the test were done. Cronbach’s alpha value of EK subscale was found as .764, Cronbach’s alpha EV subscale was found as .610 and Cronbach’s alpha value of EBI scale is .492.

Conclusions and Implications

In the questionnaire, each subscale’s Cronbach’s alpha reliability was found as .764, .610, .492 respectively. Although, the last two subscales’ reliability value was not met the recommended criteria, Cronbach’s alpha value of the full EAEBQ (α=0.710) was acceptable. In the light of these results, it can be said that the adaptation of this questionnaire successful and appropriate to use EAEBQ in the Turkish culture to determine pre-service science teachers’ Environment Knowledge (EK), Environmental Values (EV) and Ecological Behavior Intention (EBI) by taking into account satisfactory reliability and validity results .

After validity and reliability analysis of EQEBQ is appropriate to use for pre-service teachers at various grades. Predictive power of environmental attitude and knowledge in relation to ecological behavior at pre-service science teachers, and to measure the relationship between ecological behavior and environmental attitude of pre-service teachers from different departments can be examined with EQEBQ. Effects of gender on environmental knowledge, attitude and behavior should be examined as well as predictive behavior.

CONTRIBUTION TO THE DESIGN-BASED FEATURES ENHANCING ILL-STRUCTURED PROBLEM SOLVING: CAMPFIRE PROBLEMS

Yasemin Doğan[1] and Zeynep Gürel[1]
[1]Physics Education Department, Marmara University

Abstract: A design-based research was conducted in order to enhance the solution of the ill-structured campfire problem taken as cases from participants' direct experiences in nature. The solution of the campfire problem was a cyclic process which had some variations and refinement from phase 1 to phase 3. The cycles were examined in accordance with design-based research characteristics. The findings concerning the enhancement of ill-structured problem solving in the framework of design-based research were chosen. This study aims at contributing to use of ill-structured real-life problem solving including outdoors within the framework of design-based research as a pioneer study.

Keywords: Design-based research, Outdoor physics education, Ill-structured problem solving Case-based instruction.

INTRODUCTION

Design is a common method used for solving real life problems. It is a complex process, encompassing many skills and activities. Students need support to execute the various activities involved in designing successfully, such as analyzing the situation to understand the problems and issues that need to be addressed, gathering information, generating alternative solutions, generating criteria to evaluate solutions, thinking about trade-offs, and justifying choices (Puntambekar and Kolodner, 2005). Instead of a contrived curriculum presented through an artificial context, design tasks are supported by learning on demand, where learning goals emerge from the situation at hand. In other words, because design problems are ill-structured, professors cannot determine a standard curriculum until students actively devise methods for addressing the design problem (Nelson, 2003).

Most studies including real life problems take the experience students bring to class as basis. However Campbell, Lubben and Dlamini (2000) used science based everyday problems and found the percentage of responses demonstrating the use of science low particularly for students who have been taught through a context based approach, and thus they suggested that bringing 'everyday situations' into 'school science' does not readily enable students to bring 'school science' into 'everyday situations'. Similarly Fortus (2005) suggests providing students with an experience in which they apply their knowledge in real world contexts and Krupa (2002) states that the potential for educational opportunities in an outdoor classroom is limitless. Moreover an important resource for physics education still seems relatively unexplored: physics activities in `nature' (Popov, 2003) where children make meaning from their direct experiences (O'Brien and Murray, 2007). Gürel et al. (2007) argue that although it is obvious how important the outside school experience is for their profession, very few teachers attempt to make use of it, however the 'applied knowledge' they need to establish in their science classes is a connection between science and daily life.

On the other hand particularly due to the social facet of it, this study is based upon Vygotsky's Social Constructivism Theory. According to this theory knowledge is social in nature and is constructed through a process of collaboration, interaction and communication among learners in social settings (Vygotsky, 1978).

METHODS

Using design-based research methods, qualitative data were collected through field notes, open ended questions, individual and group reports and the video transcriptions of the lessons including in-class and outdoor discussions about the campfire problem within the framework of the data gathered from prospective physics teachers about the driving question during the three-year implementation period, from 2007 to 2009, as three major phases. All these phases were conducted within Area Elective 2 Course in which case-based instruction was used.

The learning environment was an integration of class with outdoor settings. The term outdoor was used as a large context including nature through one or two days residential camps, field trips and activities in campus-site as complementary experiences of residential camps. The learning environment had been arranged as a result of permanent partnerships with civil defence directorate and volunteers, participation of researchers in training programs regarding outdoor education, their collaboration with experts when needed and researchers' experience increasing year after year.

Researchers were included in the process as facilitators. Related to the campfire problem, this study focuses on the following research question: Which characteristics of design based research are evident in this study? The participants were prospective physics teachers, civil defence volunteers and experts as collaborators.

In this study contextualization was basically provided through experience and observation of the real phenomenon in its natural environment. The content of the course mainly depended on residential camp experience which was new and extraordinary for almost all students.

The real-life situations which are studied in the broader research including this study are the components of residential camp life. The broader research focuses on incorporating indoor and outdoor settings and it has covered the years from 2007 to 2009 as an incomplete PhD dissertation.

RESULTS

Many researchers used design-based or so called design research and expressed its characteristics (Collins, Joseph and Bielaczyc, 2004; Fortus et. al., 2004; Brown, 1992; Nelson, 2003; Joseph, 2004). This study evaluated more prominent ones of these characteristics which were considered to be the factors that caused variations of the campfire problem. The variety and refinement of the design as one of these characteristics is left out of this study to be described in detail in a further study.

Within this study, the implementations of the campfire problem belonging to three phases were handled as three cycles. All the cycles commenced with the same driving question and in a certain stage they were supported by residential camp experience. The cycles are given in figures 1, 2 and 3 respectively.

Each cycle was different from one another depending upon the characteristics of participating people and environment (Gürel and Doğan, 2010b), and the increasing experience of researchers. However each cycle had the characteristics of design-based research.

Basically relying upon the following characteristics of design-based research, the research question of the study was answered.

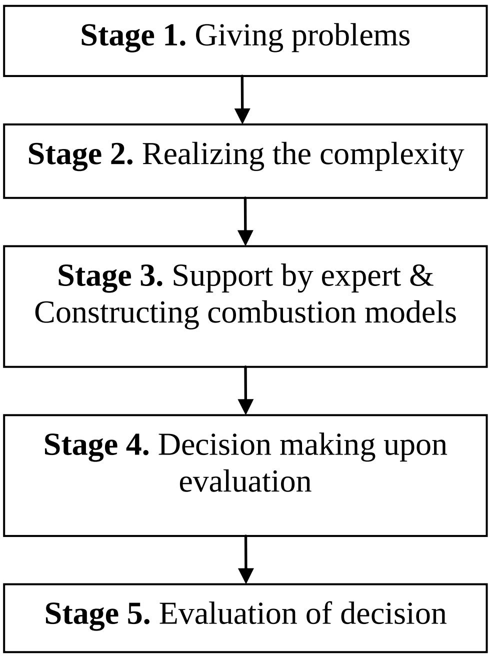

Figure 1. Cycle 1

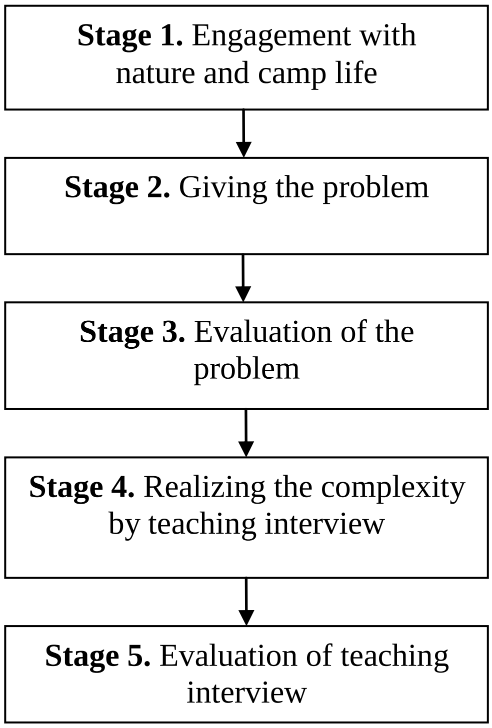

Figure 2. Cycle 2

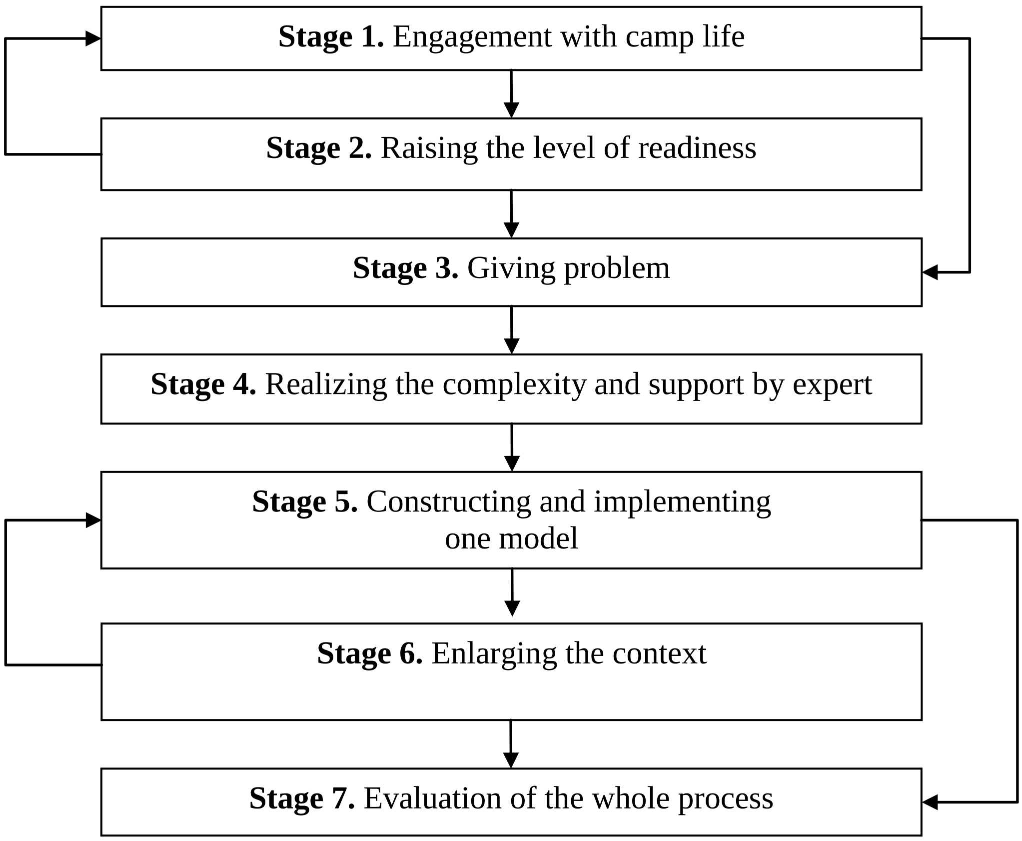

Figure 3. Cycle 3

a) There are many variables that cannot be controlled

The weather

Because it rained heavily during one of the camps in phase 2, there was an exaggeration in the description of wilderness and its adventurous aspect in students' narratives and this resulted in the formation of relevant ill-structured problem.

Unexpected events

There was a void of distractions which were present in city life including mobile phones most of the time, not because they were not allowed but because they had generally no signal. Nevertheless it was not a totally isolated learning environment because of bystanders who also affected the study. One of the most extreme examples was the death of a young man from another group, falling down a rocky hill around the campsite. Two students in our group who were also civil defence volunteers intervened in the accident and almost all members of the group also took part in the search but not rescue step of the activity.

There was a genuine collaboration between a civil defence volunteer and the instructor of the course for the organization of outdoor activities but he died unexpectedly in phase 1. It was not possible to find a civil defence volunteer who had such comprehensive knowledge of camping and who was also so highly motivated to participate in camps organized within the course. This also affected the design so that the camp, meaning that the observation and experience of the campfire, was delayed until the end of the semester in phase 1.

Complexity of the problems

There were many human and environmental factors that could not be controlled. Gürel and Doğan (2010b) revealed such factors that affect the results of the implementations for three years in a comparative analysis. The campfire problem was multivariable and even good students needed the cyclic process of design-based research to solve such a problem. When prospective physics teachers faced the problem on the incidence, they grasped the complexity and used verbal statements showing that they could not handle with it. Some of their utterances gathered in the practice of making a model campfire and discovering the variables in the campus-site in phase 1 were as follows:

Student 1: There are many variables in this setting.

Student 2: How can we control so many variables?

Henceforth, it was seen that students were unified as a group in their opinions on their emotional responses including complaint and despair.

b) Large amounts of data

The researchers were to handle with a plethora of data gathered in the broader research including this study through three cycles. However in this study we focused on the campfire, not its relation to other factors such as awareness or safety, and not the conceptions of prospective physics teachers about combustion, but the solution process of the ill-structured campfire problem. So there was a reducement in data to analyse the solution process.

c) Consultation with subject matter experts outside the classroom

Collins, Joseph and Bielaczyc (2004) insisted on the importance of the consultation with experts and stated that this gave the students access to real expertise from outside the classroom and acted to validate the importance of their research to the students. Choi and Lee (2009) aimed at developing a case-based instructional model and while implementing their model they exposed students to experts' different ideas for solutions and then asked them to refine their initial ideas for solutions.

In this study while conducting cycle 1, there became a need for deeper knowledge of an expert in the field of combustion. Then, an academic focusing on combustion in his research studies was included in the process through an interactive lecture given by him (Gürel and Doğan, 2010a). Expert knowledge was transferred to other cycles through researchers. Because having the solution of a similar problem was considered to facilitate the solution process, expert knowledge was also integrated with Faraday's lectures on candles in cycle 3. Thus burning candle problem was involved in the process as it was a similar and simpler one for the campfire problem in this cycle (Doğan and Gürel, 2010). The knowledge of building a campfire necessitated outdoor expertise and this expertise was included in all cycles.

d) Introducing the driving question

The driving question of this study was "How do you build and maintain a campfire throughout the camp?" and it was the same for all cycles. However the way of providing prospective physics teachers' engagement in the driving question varied through phases. In cycle 1 the context was set with the presentation of photographs from the camps of the previous year and the presentation of the driving question. In cycle 2, a group of students commenced to conduct research on providing outdoor resources for the needs of logistics and campfire. And they accomplished the practice through cooperation with the expertise of civil defence. In cycle 3, prospective physics teachers were exposed to the experience of building a campfire directly beforehand in a preparatory camp having a very flexible program before the initiation of group work. Moreover taking the responsibility which was a requirement of camp life disseminated to the whole settings of the course. The most prominent factors which were effective on the campfire varied through camps as well and this affected prospective physics teachers' engagement in the problem. In cycle 1, which was dependent on the implementations of the previous year through related photographs, the most prominent factor was the size of the log which had to be burned for a continuous campfire. While it was the heavy rain in cycle 2, it was the colour of the flame in cycle 3.

e) Being grounded in real-world settings

The real-life situations which were studied in the broader research including this study were the components of residential camp life. They were personally experienced and observed at camps by students, recorded by photographs and videos taken.

CONCLUSION

The need for support of an expert was evident in all cycles. It was revealed that support of experts was required in compliance with the nature of design-based research in the whole process whether it was subject matter or civil defence knowledge. During phase 1 the researchers also developed themselves in the two fields and they particularly took the role of subject matter experts in subsequent phases. The creation of the need to open the field to experts in subject matter as a research setting opened new horizons to new researchers.

It was an anchor in the research that driving questions remained the same despite the whole complexity of the process and despite the fact that it was introduced in different stages of each cycle. Likewise, in this research the driving question became one of the most significant design-based research characteristics under the control of the researchers throughout the process.

There was also a social context of this study and it was basically built around the campfire. Collins, Joseph and Bielaczyc (2004) evaluated Brown and Campione's (1994, 1996; Brown, 1992) FCL classrooms model as an example of design research. According to them Brown and Campione found that important social goals had been achieved by the design. Students came to value the expertise of others and they worked together better when they appreciated others' contributions. However in this study the expertise of civil defence enriched the social context and with this expertise the campfire appeared to be the centre of social context which consisted of nature awareness, responsibility, apprenticeship and collaboration. It was the venue where the participants ate, talked and felt safe. This social context was transferred to the class with ill-structured problem cases narrated with the aid of photographs and then physics content replaced the social context in the solution process.

The whole process was effective on the solution of the campfire problem. The differences between the cycles reflected on the solution and thus it was different in each cycle.

SEIZURE OF ATMOSPHERIC CO2: A TEACHING METHODOLOGY AIMING FOR SUSTAINABILITY

Tania Renata Prochnow[1], Maria Eloisa Farias[1] and Julio Ricardo Bastos
[1]Universidade Luterana do Brasil – ULBRA/RS

Abstract: The environmental crisis affecting the planet requires that the school search with the teaching methodologies acts in search of sustainability. This study involved seventy-five academics and aimed to develop a simplified methodology for an interdisciplinary teaching, aiming to Environmental Education for Sustainability. This methodology is sought to quantify the carbon stored in the stems of native and exotic trees, to emphasize that the obtained data can be used to support the choice of species in projects that seek to mitigate the greenhouse effect, and with features that help in recovery degraded areas. For the selection of species was based on a literature that showed the relevant characteristics of ecological and trade them. By determining the individual weight and mass density of seeds of each species, along with measurements of height, diameter and volume of adult stem was determined with the use of stoichiometric calculations the efficiency of removal of atmospheric CO_2 for each selected species . Native species have a relevant potential for carbon sequestration, as well as advantages for reclamation. This methodology allowed the experience of interdisciplinary scientific discussions in the classroom, leading students to bring their own understanding of environmental issues for the chemistry, physics, mathematics and biology disciplines, to the positions in the daily life, recognizing that beyond the technical and scientific training for the involvement of other equally important elements.

Keywords: Teaching Methodology. Carbon Sequestration. Native Species. Exotic Species. Science, Tecnology and Society (STS)

INTRODUCTION

The environmental crisis affecting the planet requires that the school search with teaching methodologies acts in search of sustainability of the earth. Observe that you can invest in a new citizenship through a learning formation involving Science, Technology and Society (CTS) is made to interact with the social rationality experiencing technical-scientific rationality decision-making more participatory methods (SANTOS, 1999).

It is a fact that burning fossil fuels and fires resulting from deforestation, which occurred with greater intensity in the last 150 years due to industrial revolution and population growth have been the major cause of carbon dioxide (CO_2) emissions into the atmosphere (GOLDEMBERG, 1998). This gas, along with others, such as water vapor (H_2O), methane (CH_4), nitrous oxide (N_2O) and chlorofluorocarbons (CFCs), are known as greenhouse gases (GHGs), which form a mixture of gases retain solar heat in the atmosphere.

The greenhouse effect is a naturally occurring phenomenon. The layer of atmospheric gases have a vital role in how solar radiation interacts with the Earth, causing the temperature remains steady and there is life on the planet (SCARPINELLA, 2002), but the model of production and energy consumption has been adopted greatest contribution to the anthropogenic forcing of climate due to the intensive use of fossil resources are not renewable. The amount of carbon released by burning fossil fuels is accelerating, but the kidnapping of the same amount of fossil carbon in the environment, took millions of years to form these fuels (CALDAS, 2004).

Rocha (2002) notes that "the Clean Development Mechanism - the CDM, have a double objective: the reduction of GHG emissions and / or carbon sequestration, and promote the sustainable development of the country hosting the project.

Within the context of the CDM, has been taken into account the importance of forests as a compensatory measure the emission of greenhouse gases. It is scientific consensus that global forests are important for the global carbon balance, as stored in trees and soil carbon more than what currently exists in the atmosphere (HOUGHTON, 1994). For Brazil, in particular the Clean Development Mechanism can be very interesting, since it takes a great potential for Brazil to produce clean energy, and allows the country to play important role in international environmental (VIDAL, 2003).

The plants, using its photosynthetic capacity, fix atmospheric CO_2, biosynthesized in carbohydrates form, and finally deposited in the cell wall, process known as "sequestration" of carbon (RENNER, 2004).

Brazil has the largest diversity of the world. The lack of technical direction and ecological awareness in the exploitation of our forest resources has caused irreparable damage and ecologically valuable species are endangered (LORENZI, 1998). Given this focus, Brazil may take a privileged position in relation to countries that seek to reverse the process of global climate change.

OBJETIVES

This study objectives to build a teaching methodology that allows simplified review and assess the photosynthetic efficiency in the removal of atmospheric carbon dioxide using native and exotic trees, seeking to obtain meaningful data for selection of plants with significant potential for carbon sequestration.

TEACHING METHODOLOGY

This study was conducted with seventy-five students in the Bachelor of Biology course, with emphasis in Ecology, in Canoas-RS-BR, aimed to arouse the awareness of students in order to the problem of climate change, by building an interdisciplinary methodologies for education that promotes the search for alternative solutions aimed at sustainability and the mitigation of anthropogenic environmental effects.

Through literature research using journals, books, papers and publications were researched the characteristics of plants from native and exotic species in relation to their needs change, parameters of soil quality, ease of obtaining germination of the seeds, and forms of plant propagation and establishment of growth time.

Considering that the main components of the tree trunk are polymers consisting of carbon, hydrogen and oxygen, in proportions represented by monomer CH_2O, we used this as the basis for the stoichiometric and statistics calculations, aimed at simple teaching, easy to understand by students and to demonstrate the photosynthetic mechanism of removal of atmospheric CO_2.

Through the characterization of the selected species and literature based on survey data, we selected species with appropriate characteristics to the soil and climate of Rio Grande do Sul, Brazil. The literature data, stoichiometric calculations and statistics were used in calculations of CO_2 remove potential from each selected species. We selected the native trees called <u>Cabreúva-amarela</u> (*Myrocarpus frondosus*), <u>Brazilian Cedar</u> (*Cedrela físsilis Vell*), Brazilian Pine (*Araucária angustifólia)* and Louro Pardo (*Cordia trichotoma*) and even the exotic Pinus (*Pinus elliotii*) and Eucalyptus (*Eucalyptus grandis*).

RESULTS

According to the calculations used to estimate the efficient removal of atmospheric CO_2, based on the equation of photosynthesis monomer, it was found that the species most remove and quantify its trunk in atmospheric CO_2 during its development period until the climax *Araucaria angustifolia* were the native and exotic *Eucalyptus grandis* (figure 1).

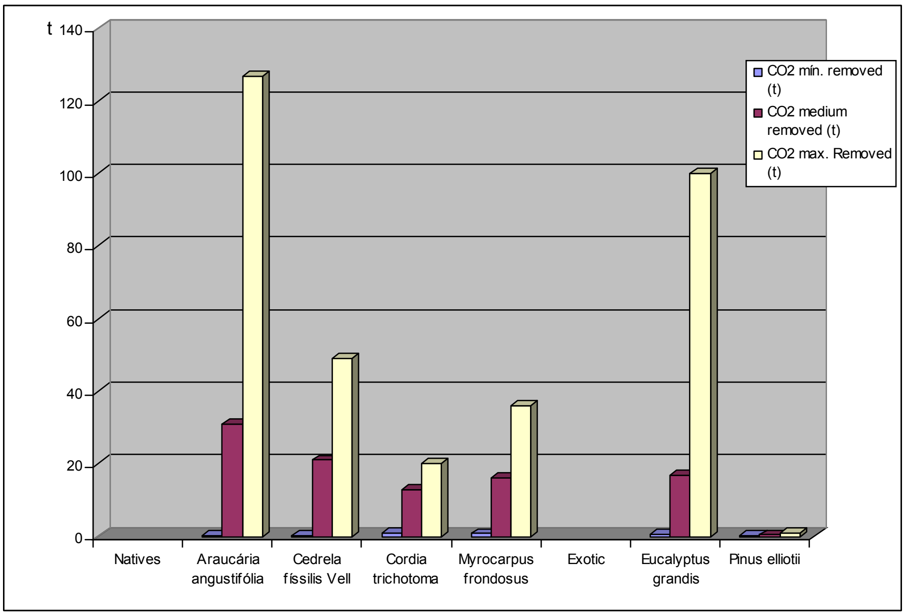

Figure 1. Minimum, average and maximum values of Co2 removed potential (in tons) for each species in study.

The applied methodology provided to the students the agreement of the relation of applicability of the theory in the practical one, enabling them to take it decisions in its future professional life, in relation to the atmospheric carbonic gas removal potential by the more efficient species, aiming at the Sustainable Development.

CONCLUDING REMARKS

The results of this study confirm that native species have significant potential to remove atmospheric CO_2, compared with the principal alien used for timber and pulp industry, taking into account soil and climatic characteristics and possibilities that each one offers.

The research has been useful to scholars, to compare the ability of atmospheric carbon removal between species, to enable scientific discussions branches based on the Science, Tecnology and Society - STS movement, which allowed closer understanding of the theme developed in the academic disciplines to the positions they occupy everyday life, recognizing that beyond the technical science there are other equally important elements to their training.

ENVIRONMENTAL IMPACTS AND EDUCATION FOR SUSTAINABLE DEVELOPMENT IN PUBLIC SCHOOL

Maria Eloisa Farias[1], *Tania Renata Prochnow*[1] *and Ana Paula Chies*[1]
[1]Universidade Luterana do Brasil - ULBRA

Abstract: Projects in Environmental Education (EE), developed in schools, aimed at forming an environmental conscience, trying to modify the human relationship with nature and achieve a balance to promote Sustainable Development (SD). The pedagogical activities of EA, for its interdisciplinary character, enclose environmental and exact sciences, social and cultural subjects, political, ethical, historical and others. The principles of EA declared in Tbilisi Conference (UNESCO & UNEP, 1978) have included the key elements for the DS: the need to consider the social aspects of the environment and relations between economy, environment and development, the adoption of local and global perspectives and the promotion of international solidarity and others. Because knowledge is a human construction and depends on the interaction between individuals, working in the school's approach to historical topics of the environmental sciences, can motivate students to ask questions and be more critical relationship to the presented information. Only with the active participation of various society sectors, committed to planning a desire for positive change, that one becomes possible to revert the current model and to seek social justice and environmental balance (DIAS, 2004). This project ,based in action research methodology, aims to develop the teaching strategies in Environmental Education for Sustainable Development, with the target population attended by public schools in the outskirts of Canoas-RS/BR.

Keywords: Environmental Impacts. Education for Sustainable Development. Environmental Education. Pedagogical Strategies.

INTRODUCTION

For Mendes (2006) and Leff (2006, 2002) Sustainable Development occurs when there is effective balance between technology and environment, revealing to the various social groups of a nation and also the different countries in search of equity and social justice. Towards effective Sustainable Development although, second Leff (2006), would require building styles of development based on a new "productive rationality", so that the dominant economic policy incomes in the creation of poverty reduction politics and programs to strengthen productive self-management, with regard to the relationship of dependence that keeps with the state.

There is almost unanimous consensus that the guidelines point toward the formation and empowerment of communities, whether for self-management, is for reorganize the productive arrangement. For Sauvé (1997), Environmental Education is closely linked to Sustainable Development, and production subsidies for the organization and development of new methodologies to be applied in the training of professionals in environmental education, emerged in the theoretical and practical truly interdisciplinary experiences. Is both feasible and practicable, that environmental education included in the Tbilisi Conference (UNESCO & UNEP, 1978) already included the key elements for Sustainable Development: the need to consider the social aspects of the environment and their relationships between the economy, environment and development, the adoption of local and global perspectives and the promotion of international solidarity, the humanistic approach, etc.

In Brazil there are laws like the 9795/99 and 4281/99 decree establishing guidelines and criteria that will encourage and enforce the environmental education efforts. This Act 9795/99 trats of the National Environmental Education and Decree 4281/02 that regulates the National System of Environment (SISNAMA). There are also documents as the Treaty on Environmental Education for Sustainable Societies and Global Responsibility prepared during the ECO-92, signed by several countries, aiming to guide the environmental education practices around the world, and also international documents such as those generated in Stockholm (1972), Tbilisi (1977), and the Global Agenda 21 (1997), somehow both recommend that the EE should have an interdisciplinary and humanistic approach and be developed at all levels within and outside schools.

In studies of Grün (2000), there is a very pertinent question to debate. The appreciation of the concept and the tradition within educational theory can contribute to the integration of environmental education in culture and language, making it something organic and common to a given bioregional medium. However it is observed that in school, Environmental Education becomes possible and timely, appearing as a phenomenon that occurs due to biotic or abiotic interference or large commotion in front of an imminent catastrophe. This coincidence, coupled with the lack of integrated planning and scheduled projects that contribute to environmental education is seen as superficial and fleeting.

It is therefore necessary to identify human actions and their environmental effects in the region and at school, researching historical interferences, economic and social changes that allow to define and analyze the environmental impacts generated by urban sprawl, then propose to develop and invest in Environmental Education for Sustainable Development and healt. By analyzing these factors we chose to use different teaching strategies, seeking an interdisciplinary context as practical classes and field trips, investigating the possibility of incorporating the students' practice and reflection on actions related to the surrounding environment, emphasizing the importance to their life quality by developing themes of the EE for the exercise of citizenship with environmental responsibility.

OBJETIVES

This project, based in the methodology of action research, aims to develop the teaching strategies in EE for Sustainable Development, with the target population attended by public schools in Canoas-RS/BR, through the following objectives:

- use different teaching strategies, seeking an interdisciplinary context as practical classes and field works;

- investigate the possibility of incorporating the students practice and reflection on actions related to the surrounding environment;

- emphasize the importance to their life quality by developing themes of the EE for the exercise of citizenship with environmental responsibility

METHODOLOGY

This work is grounded in action research, a kind of empirically based social research, designed and carried out in a closed association with an action or collective problem solving, in which researchers and representative participants of the situation or problem are involved in a cooperative or participatory action (THIOLLENT, 1997).

The steps hab been: detection of the problem, interaction, theme generation, monitoring decisions and actions, problem solving and the level of consciousness. Data collection was performed using the search to the theoretical framework, environmental zoning, collecting historical data and regional environmental impact studies, field works and photographic records. We also developed experimental activities with the target population, initiated with the implementation of a Data Collection Instrument (DCI) involving students in the School Hall Carlos Drummond de Andrade, in classes 5 and 6 years of elementary school. The DCI used was a questionnaire for population characterization and socio-environmental knowledge, including the health subject.

After, we used lectures and videos on the socio-environmental issue facing the regional reality, in order to rescue the historic formation of the district and establishment of the local community, encouraging reflection on the current problems. The next action was to encourage students to search information on the socio-environmental problems, usually found in their homes or in the coverage areas, stimulating the construction of personal experiences in this regard.

RESULTS

The results led to the realization of a Science Fair where participants socialized their experiences on the covered topics (Figures 1 and 2). To evaluate the results of this action research, we applied a new DCI, to evaluate the methodology applied. We identified a severe deficiency in the students' knowledge construction about the environmental impacts caused in his neighborhood.

Figure 1. Students Presenting results to the GARBAGE problem

After the accomplishment of the sensitization speak and videos exposition, was observed an increment in interest on the thematic, that culminated in the exposition of works made by students in the sciences fair.

Figure 2. Objects confectioned with recycled residues

For this fair, other pupils groups and residents of the district also had been invited as visiting, aiming to increase the scope of the impact of the methodology applied in the school.

CONCLUSIONS

The study enabled the observation of a sharp increase in the perception of environmental issues by the school community involved. We can affirm that developed a pedagogical action beyond the classroom, in a dynamic and opened study to social and cultural diversity, which attracted, involved and is appreciated by students, that working with commitment and social responsibility.

INFLUENCE OF A NON-FORMAL ENVIRONMENTAL EDUCATION PROGRAM (GREEN COUNCIL PROGRAM) ON PUPILS' ENVIRONMENTAL LITERACY

Daphne Goldman[1] and Orit Ben-Zvi Assaraf[2]
[1] Beit Berl Academic College, Israel
[2] Ben Gurion University of the Negev, Israel

Abstract: One solution implemented by schools in Israel to conduct value-based environmental education is outsourcing- allocating out-of-school environmental organizations that develop and conduct environmental education programs. This study addressed such a program - the Green Council Program (GCP) developed and implemented in schools by the Israeli Society for Protection of Nature. It investigated, in a pretest-posttest design, influence of participation in the GCP on components of junior high-school pupils' environmental literacy. Conceptualizations of 'environment', environmental attitudes and sense of ability to act on environmental issues were studied employing quantitative and qualitative tools.
The program did not develop a systemic understanding of 'environment': pupils perceive the environment mainly in biophysical terms and this remained changed, and perception of interactions between organisms and their environment through processes of material or energy flows was limited and remained unchanged. On the other hand, the GCP heightened pupils' sensitivity to human–environment interrelationships and developed a more ecological worldview: after the program, pupils demonstrated greater perception of man as part of the environment, increased sensitivity to human impact on the environment and their value for non-human nature moved from an anthropocentric to a more ecocentric orientation. In spite of the fact that pupils' internal locus-of-control increased, when environmental protection entailed personal economic trade-offs, their support was limited and remained unchanged by the program.
Findings of the study provide empirical evidence to effectiveness of the GCP in achieving its stated goals and in developing components of environmental literacy. They also have broader implications with regards to developing and implementing non-formal environmental education programs in schools as extracurricular programs supplementing the school (science) curriculum, and their effectiveness in achieving all the recognized goals of environmental education.

Keywords: Environmental education; environmental literacy, non-formal education, junior high school students, perceptions of environment

INTRODUCTION

Education is recognized as an implementation strategy for achieving sustainable development (UNESCO, 2004). In 2003, sustainable development was formally recognized in Israel as a national policy to be implemented by all Ministries (Ministry of Environment, 2003). Since then, environmental education for sustainability (EEfS) has been included as a goal of education (Ministry of Education, 2004). Challenges for the educational system in responding to prioritizing of EEfS are considerable, such as how to conduct effective EEfS and within which frameworks? Science education is targeted as a main subject for including EEfS and developing environmental literacy is currently recognized as one of the goals of science education. Practical issues arise in addressing meaningful EEfS within science education. For example: standards- based science education compounded by time constraints encounters difficulties in addressing the diverse dimensions of EEfS such as educating for values and developing environmental citizenship. Questions relate to teacher preparation - are science teachers sufficiently equipped to address meaningful EEfS?

One solution schools take to conduct value-based EEfS is outsourcing - allocating out-of-school environmental organizations that develop and conduct environmental education programs as one tool to realizing their goals. This study addressed such a program. The 'Green Council' Program is an environmental education program developed and implemented in schools by the Israeli Society for Protection of Nature (SPNI). The GCP is based on non-formal education attributes (Eshach, 2006) and on the SPNI educational model 'From experiencing wonder to action' (Gan, Pizmony & Peled, 2002) aimed at developing environmental-social activism in young people. The 'Green Council' is a group of pupils motivated to promoting environmental change in their school and local community. These pupils and their teacher convene with an SPNI instructor after school hours throughout the school year to work on local environmental issues. GCP is not part of the school curriculum, is taught by an SPNI instructor and student participation is of free will.

The present research was conducted in a junior high school in the major city of southern Israel that implements the SPNI environmental education program. It aimed to investigate influence of participation in the GCP on components of pupils' environmental literacy. Specifically, the study addressed pupils' understandings of the concept 'environment', their attitudes regarding the value-of-non-human-nature, positions on priorities for resource management and their sense of ability to act on environmental issues.

METHODS

Participants

The study was conducted in a paired pretest-posttest design with 50 7^{th} and 8^{th}grade pupils (25/grade) who participated in the GCP. They were average to strong pupils.

Instrumentation

The study was based on the mixed-methods approach employing a combination of quantitative and qualitative tools. Conceptualizations of 'environment' were investigated with the Draw-an-Environment Test (Shepardson, Wee, Priddy & Harbor, 2007) and the Word Association procedure (Hovardas & Korfiatis, 2006; Ben-Zvi Assaraf & Orion, 2009) in which terms provided by pupils to the stimulus term 'environment' reflect their patterns of thought. Attitudes regarding value-of-nature, positions on priorities for resource management and locus-of-control for environmental action were investigated by a combination of the likert-type environmental attitude questionnaire (Pe'er, Goldman & Yavetz, 2007, Yavetz, Goldman & Pe'er, 2009), written explanations for questionnaire items and the Repertory Grid technique (Bezzi, 1999) which depicts the individual’s way of thinking. In the repertory grid technique, participants randomly chose series of 3 terms from their word associations, for each series chose a term they perceive as exceptional and provide an explanation why.

A combination of tools enabled data triangulation thus enhancing validity of results and providing more comprehensive information on changes occurring in pupils’ environmental literacy.

Data analysis

Shepardson's et al., (2007) typology of mental models of environment was used for analysis of drawings. Different mental models reflect various ways in which pupils perceive 'environment'. Analysis of word associations used an inductive content analysis procedure (Ben-Zvi Assaraf and Orion, 2009). Analysis of repertory grid data was based on Ben-Zvi Assaraf and Orion (2009). For validity, researchers analyzed data individually and only categories agreed upon were included. For quantitative data, means, standard deviations and distributions were determined and paired t-tests were used to examine differences between pre-test and post-test groups.

RESULTS

Perceptions of 'environment'

Analysis of drawings of 50 pupils shows that in the pre-test group the most prevalent mental model (36%) was that which expresses a romantic perception of the environment as pastoral nature in which man has no part. In the posttest there was a 39% decrease in drawings reflecting this mental model. Most pupils, in both the pretest and posttest, portrayed the environment in biophysical terms, as an ensemble of components and very few expressed processes of energy or matter flow. Thirty percent of the pretest drawings corresponded to a mental model which perceives man as part of the environment in a harmonious relationship with other organisms. A 33% decrease was found in this mental model in the posttest in spite of the fact that one aim of the GCP is to evoke a feeling of human oneness with nature. Fewer drawings in pretest group (18%) corresponded to the mental model which perceives the environment as life supporting - a place providing the resources necessary for living organisms, and no change occurred in the frequency of this mental model in the posttest. This mental model reflects perception of interactions between organisms and their environment, hence it expresses a more developed and systemic understanding of the environment, relating not only to tangible components but also to interactions between them through processes basic to sustaining life. This may explain the limited frequency of this mental model. Sixteen percent of the pretest drawings corresponded to the mental model which perceives the environment either as a natural place impacted by man or as manmade. This was the mental model most influenced by the GCP: a nearly 3-fold increase occurred in the number of drawings portraying this mental model after participating in the program.

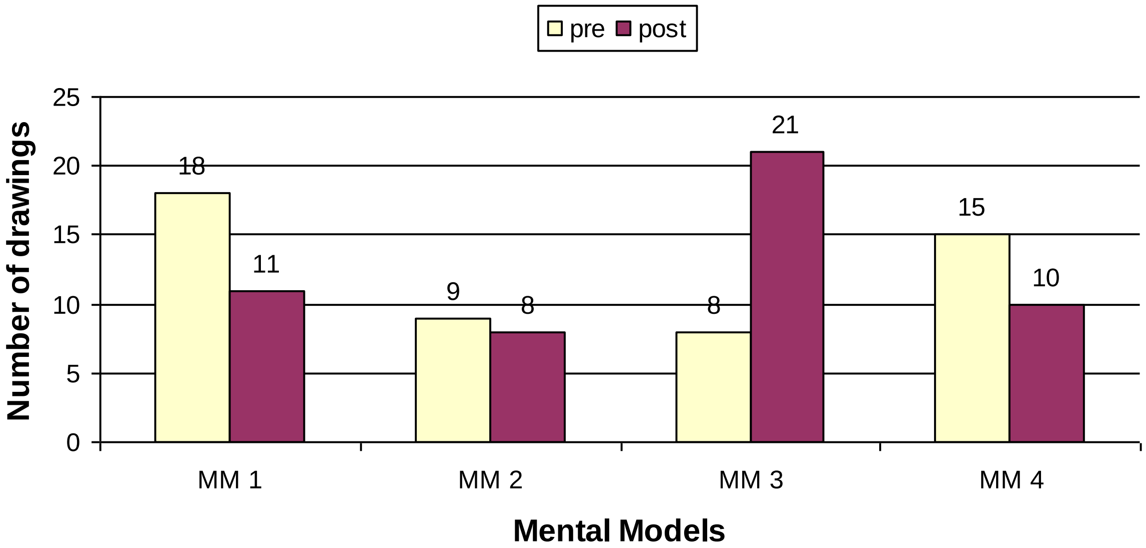

Figure 1. Distribution of students' drawings and explanations of 'environment' based on the Mental Models (MM) described by Shepardson et al., 2007 (MM1 - A natural place where

animals or plants live, MM2 – Supports life, MM3 – A place modified or impacted by man, MM4 – A place where plants, animals and people live).

Content analysis of concepts provided by pupils in their word associations to the prompt term 'environment' revealed four major categories reflecting different ways pupils perceive and understand the concept 'environment': a) biophysical - terms related to physical or biological aspects, describing the environment as an ensemble of components; b) social - terms relating to human aspects of environment; c) romantic - nature, pastoral-related terms; d) environmental protection - terms relating to man's intervention - a place man-managed or in need of protection from human impact. Similar to the results obtained in the draw-an-environment test: 1) The predominant category in both the pretest and posttest was the biophysical (44% and 31%, respectively); 2) Environmental protection was the least frequent pretest category (11%) and the largest change (2-fold increase) occurred in the frequency of this category in the posttest (25%).

Value-of nature

Results of the attitude questionnaire indicate that pupils moved from a more anthropocentric orientation in the pretest to a more ecocentric orientation in the posttest. For example, in the pretest, two thirds supported the position that the value of organisms is determined solely by the benefit they provide man, while in the posttest there was significant decrease in the utilitarian value of organisms ($t=4.36$, $p=.001$). Results of the repertory grid correspond to those obtained in attitude questionnaire: 61% of the constructs created by pretest pupils reflected an anthropocentric approach while in posttest, 63% of constructs reflected an ecocentric approach.

Priorities for resource management

Pupils' support for environmental protection was strongest and most influenced by participation in the GCP ($t=2.53$, $p=.007$) when this was presented as a general priority. Support for environmental legislation that puts constraints on personal lifestyle was less pronounced and change in pupils' position between the pre and posttest was more limited ($t=1.74$, $p=.04$). When implications of environmental protection were demonstrated at a personal level, in terms of trade-offs between environmental protection and economic benefit, or between environmental protection and leisure activities, the students expressed less support for protection and no change occurred between pretest and posttest ($t=1.25$, n.s. and $t=1.92$, n.s.)

Self efficacy to act on environmental issues

Pretest pupils displayed overall sense of self-efficacy to positively effect the environment through their personal behavior and this was further enhanced in the posttest. For example, 40% disagreed with the statement 'Responsible environmental behavior won't make a difference because the impact of others is too great' in the pretest and disagreement increased significantly in the posttest ($t=2.49$, $p=.008$).

CONCLUSIONS AND IMPLICATIONS

This study investigated influence of participation in the Green Council environmental education program on aspects of junior high school pupils' environmental literacy. Regarding comprehension of the environment, results indicate that the program did not develop a more complex understanding of this concept: perception of the environment mainly as an assemblage of biophysical components remained unchanged; perception of interactions between organisms and their environment through processes of material or energy flows, which reflects a more complex understanding of the environment not only in tangible biophysical terms but as processes, was limited and remained unchanged. On the other hand, results indicate that the program heightened pupils' sensitivity to human–environment interrelationships and developed a more ecological worldview. After participating in the program, pupils demonstrated greater perception of man as part of the environment, increased sensitivity to human impact on the environment, and their environmental values, reflected in their value for non-human nature, moved from an anthropocentric orientation to a more ecocentric orientation. One of the aims of environmental education is to move individuals in this direction on the anthropocentric-ecocentric continuum. An important component of environmentally literate individuals is their self efficacy, and one purpose of environmental education is to empower people with belief in their ability to contribute to environmental solutions through personal behavior. Participating in the program increased pupils' internal locus-of-control. The strong sense of self efficacy demonstrated by pupils before the program may reflect attributes of these motivated adolescents and their environmental orientation motivating them, in the first place, to participate in the program. When environmental protection had personal economic implications, pupils' support was conservative and remained unchanged by the program. While this result appears to stand in contrast to their increased environmental sensitivity, it may reflect their limited understanding of the environment. Support for personal sacrifice reflects conceptual awareness of how human behavior affects the environment, i.e. the person understands that resources are limited, comprehends personal implications of conserving limited resources and is willing to make personal sacrifices necessary to conserve resources. And visa versa (Pe'er et al., 2007).

Goals of the Green Council Program focus on the affective components of environmental literacy - environmental values and attitudes. Its focus is not on developing knowledge since the case studies chosen for schools are based on relevant ecological, environmental concepts studied in the science curriculum. Results obtained in the study support contribution of the GCP to developing affective components of environmental literacy. The findings also support the importance of the knowledge component in promoting commitment to responsible environmental behavior as reflected in the willingness for changes in personal lifestyle.

Findings of this study provide empirical evidence to the effectiveness of the Green Council Program in achieving its stated goals. They may have broader implications with regards to developing and implementing non-formal environmental education programs in schools as extracurricular programs supplementing the school (science) curriculum, and their effectiveness in achieving all the goals of environmental education for sustainability.

FINNISH PUPILS' CONCEPTIONS OF THE IMPORTANCE OF NUTRITION, SLEEP AND EXERCISE FOR THEIR WELL-BEING

Eila Jeronen[1], Tuomas Luukkonen[1], Juha Roininen[1] and Juha Jeronen[2]
[1]University of Oulu, Finland
[2]University of Jyväskylä, Finland

Abstract: Nutrition, sleep and exercise are extremely important factors for health. New studies have shown that obesity is common, pupils do not sleep enough, and their fitness is not good. School-based health education would produce positive effects on beliefs, attitudes and behaviour, if it was known what pupils think about these issues. This paper reports the results of a study where the pupils' conceptions of the importance of nutrition, sleep and exercise for their well-being were investigated. The study was a quantitative descriptive survey, in which a total of 203 pupils (11–12 years old) participated voluntarily. The resultant data was collected using a semi-structural questionnaire in 2009. The data was analysed by using SPSS and Excel and tested with the Student t-test. Based on the results, most of the pupils found their health to be good or very good. They understood that healthy food, sleep and exercise are important. They ate well every day, but more in the afternoons and evenings. The girls appreciated healthy food more than the boys. The pupils thought that sleep is important for feeling well. They slept over eight hours per night. Over 60 per cent thought that exercise is important for welfare, good mood and physical fitness. The boys exercised more than the girls. Based on our results, it seems that the most important topics to be included in the curriculum and in the teaching, learning and studying processes of health education seem to be those which are especially related to mental and social welfare. In addition, significance of rest and sleep to health and the importance of breakfast and school meals for concentration and feeling should be discussed more at school.

Keywords: sleep, nutrition, exercise, health, pupils

INTRODUCTION

Core themes in research are the connections of education with health and well-being (Lappalainen et al., 2008). The most commonly quoted definition of health is that presented in the Constitution of the World Health Organization (WHO, 1996): "Health is the state of complete physical, mental and social well-being and not merely the absence of disease or infirmity". Well-being has a personal and an objective side. The former consists of one's own experiences of one's health, the latter of external factors such as livelihood, education, safety and social relationships. (Rimpelä et al., 2007) According to Jeronen, Kaikkonen, and Lindh (2008, 111), the majority of 11–12 years old Finnish pupils felt that they were in good health. They explained their good health with lack of illness, good feelings and having the strength to live. Important factors for health are nutrition, sleep and exercise.

Eating habits are adopted in childhood and are very difficult to change (Ojala, 2004, 83). They are affected e.g. by nutrition knowledge, family and peers. The recommendation for the eating cycle is five to six times per day (Pethman & Ilander, 2006, 22). All Finnish pupils in comprehensive schools are offered a free warm lunch at the school refectory every schoolday. Skipping meals appears not to be common among Finnish pupils aged 10–11 years. A considerable proportion consumes sweets frequently and vegetables infrequently.

(Haapalahti et al., 2002) The eating of vegetables and fruits of 11-year-old boys and girls decreased in 1986−2002 (WHO, 2009). The drinking of milk also decreased in 1990−2002 (Ojala, 2004, 92−93). According to Jeronen, Marjeta, and Jeronen (2010), girls appreciate healthy food more than boys.

The sleeping habits of pupils are dependent on their family, friends, school, and their own internal feelings. The length of the sleeping time should be about 9 hours per night (Partinen & Huovinen, 2007, 30). From 1984 to 1990, every tenth 13-year old went to bed earliest at 11 p.m. On average, the length of sleeping time was 8 hours and 15 minutes in 1994−2002. From 1990 to 1998, morning tiredness increased and in 2002, 30 % of the boys and 40 % of the girls felt tired in the morning. (WHO, 2009) Girls were more tired than boys (Tynjälä, 1999).

According to Fogelholm et al. (2007, 26−35), about 90 % of the boys and about 80 % of the girls among Finnish pupils aged 9−12 (n=2255) exercised for at least one hour per day in 2001−2003. In 1986, 40 % of the boys and 20 % of the girls and in 2002, 45 % of the boys and 30 % of the girls had physical activities at least four hours per week (Vuori et al., 2004, 124−125). About half of Finnish children participate in sport clubs on a regular basis, and four children out of five have participated sometimes (Opetusministeriö, 2008, 15). Based on the common recommendations, physical activities should make up 1−2 hours per day (Nuori Suomi, 2008, 17−20). Regular physical exercise has been characterized as a positive health behaviour, having physiological and psychological benefits (Hassmen et al., 2000, 17–25).

The Finnish comprehensive school curriculum framework for years 1–9 defines the aims and key contents of different subjects and thematic entities, and provides guidelines concerning student evaluation. The objective is uniform basic education, i.e. a continuum throughout the years 1–9 (pupils aged from 7 to 15 or 16 years) (National Core Curriculum for Basic Education, 2004). The National Core curriculum forms the basis for drawing up local curricula, which is usually done by the municipalities. Based on the local situation teachers design a curriculum for their schools and pupils taking into account the needs of the pupils and teaching, studying and learning possibilities in the area. For the first time, student welfare has been included in the curriculum. A new school subject is health education, which is to be taught as an independent subject starting in the seventh form. In the forms one to six, health education is incorporated into other subjects such as environmental and nature studies, biology, chemistry, physics; and physical education.

The study is of interest because nutrition, sleep and exercise habits, and especially overweight have developed into a major health concern over the past few decades (International Obesity Task, 2004; Currie et al., 2008; Barnekow & Muijen, 2009; WHO, 2009). Health promoting habits adopted in childhood pave the way for good health in adulthood, and decrease the risk of many diseases. Based on the Finnish Basic Education Act (628/1998): ”The purpose of education … is to support pupils' growth into humanity and into ethically responsible membership of society and to provide them with knowledge and skills needed in life.” Researchers have shown that school-based health education is capable of producing positive effects on beliefs, attitudes, and behaviour (Downie *et al.*, 2000, 111). For the development of school-based health education, it is important to know the conceptions of the pupils, because these conceptions have effects on the learning of new issues and on the construction of new conceptions (Sormunen, 2004).

The main purpose of the present study is to describe young Finnish pupils’ understanding of their own nutritional, sleeping, and physical exercise habits. In addition, it will be studied how these conceptions are different compared to their everyday life behaviour and the nutritional and physical exercise recommendations.

The following research questions guided this study:

1. How do the pupils understand the concept of well-being and how do they experience their own health?
2. How do the pupils understand the effects of eating habits on their well-being and what kind of eating habits do the pupils have?
3. How do the pupils understand the effects of sleep on their well-being and what kind of sleeping habits do the pupils have?
4. How do the pupils understand the effects of exercise on their well-being and what kind of exercise habits do the pupils have?

MATERIAL AND METHODS

This quantitative descriptive survey involved a total of 203 pupils (11–12 years old, 107 boys and 96 girls) from two primary schools in northern Finland (Hirsjärvi et al., 1997, 189). The pupils participated voluntarily in the study. The data was gathered using a semi-structural questionnaire in the autumn of 2009. At the beginning, the pupils were given guidelines and a possibility to ask about the questions. Then they were given 20 minutes to complete the questionnaire. The resultant data were analysed quantitatively using SPSS and Excel, and were tested with the Student t-test.

RESULTS

Based on the results, the pupils considered the concept of health from the physical point of view (Fig. 1). They linked it with regular exercise, healthy eating habits, good condition, and sufficient sleep. Most of them also linked health with social relationships. However, it seems that the pupils understand health mostly as a physical condition and that for them, health as a state is the opposite of illness. All the pupils felt that their own health was good.

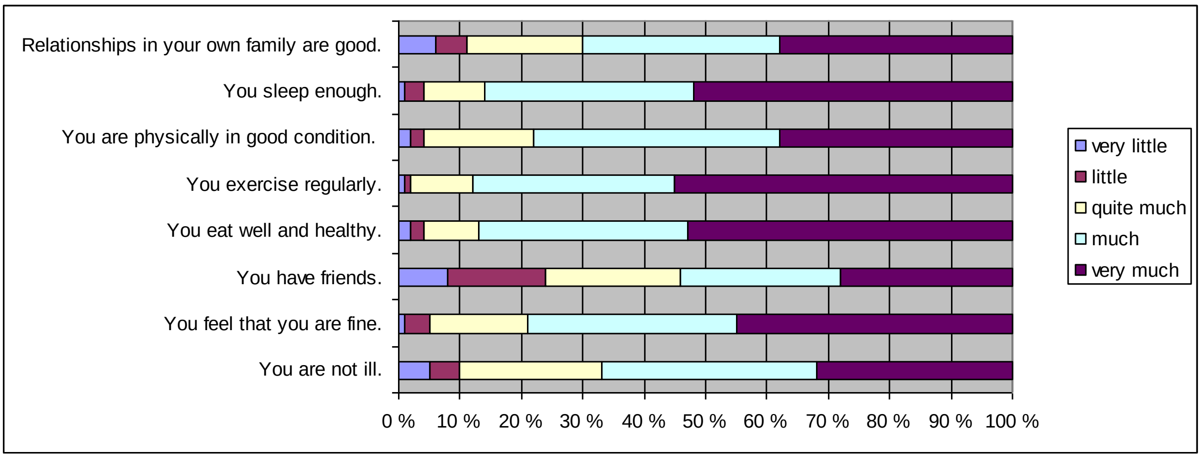

Fig. 1. The pupils' conceptions of health.

Based on the pupils' answers, food is important for feelings and health (Fig. 2). They did not emphasize nearly at all its meaning for concentration, mood, and weight management. 98 % of the pupils informed that they eat both lunch and dinner, but more in the afternoons and evenings. The girls appreciated healthy food more than the boys. However, the difference between the groups was not statistically significant.

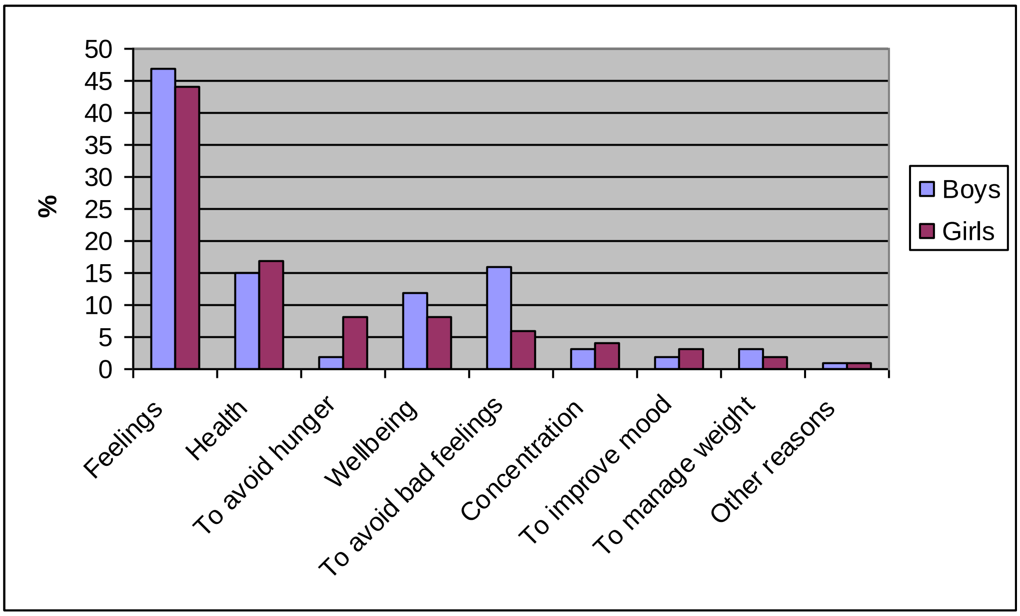

Fig. 2. The pupils' conceptions of the effects of eating on their well-being.

The sleeping habits were investigated by asking how sleep and well-being were linked with each other, and at what time the pupils went to bed in the evening and woke up in the morning. Most of the pupils stressed the importance of sleep, saying that it supports a good feeling (Fig. 3). Quite a few pupils also maintained that it helps concentration and improves their mood. Only some of them observed the importance of sleep for health and well-being. The pupils slept for 8 hours and 15 minutes on average.

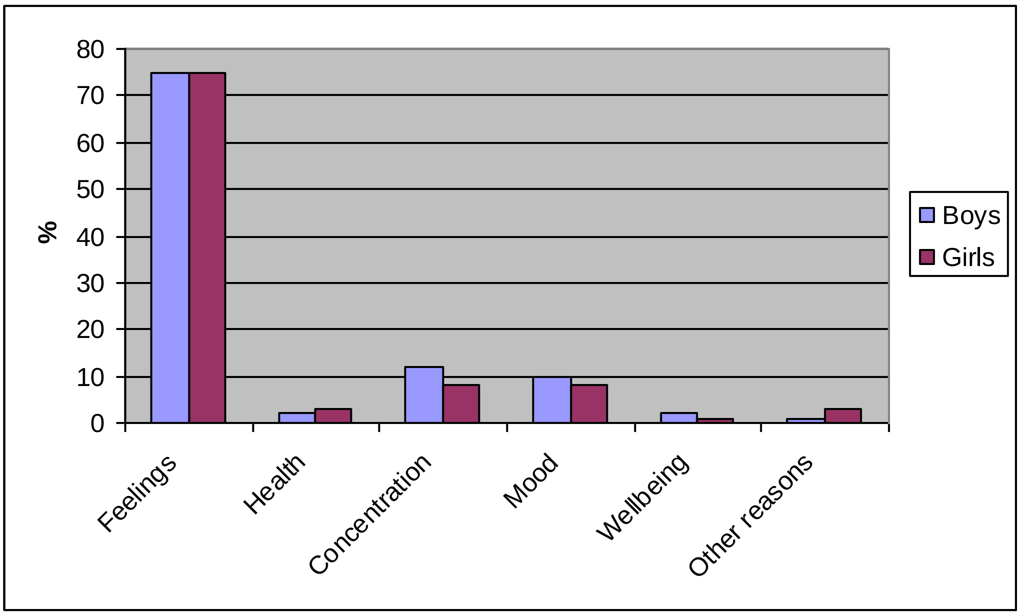

Fig. 3. The pupils' conceptions of the effects of sleep on their well-being.

The pupils linked exercise with fitness, good mood, power, and better health (Fig. 4). The boys stressed more the effects of exercise on well-being than the girls. They also had more exercise than the girls. Only a few boys and girls linked exercise with sleep and concentration. No statistical differences between the groups were found. 50 % of the boys and girls participated regularly in physical exercises at school, in their spare time and in exercise clubs.

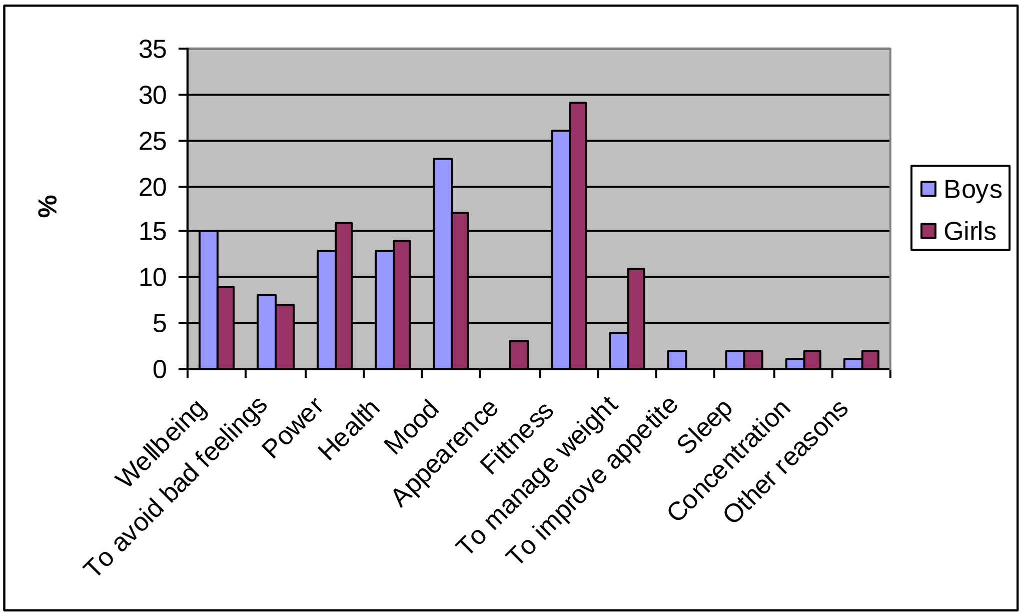

Fig. 4. The pupils' conceptions of the effects of exercise on their well-being.

CONCLUSIONS AND IMPLICATIONS

An important outcome of the study is the information gained about the understanding that pupils have about health. These issues are important in the context of planning and reconstructing school environments and curricula of health education. The pupils understood health mainly as a physical condition, i.e. in the same way as it is determined by WHO (1996). The central basis for learning and developing is how pupils feel about the state of their health (Kemppainen, 2001). The pupils thought their own health to be good. The result supports the findings by Jeronen et al. (2008).

The pupils' eating habits are in accordance with the common recommendations. The finding that the girls appreciated healthy food more than the boys supports the result of Jeronen et al. (2010). The reason may be that Finnish girls work more in the home kitchen than boys do.

According to Tynjälä (1999), unhealthy sleeping habits, sleep difficulties and tiredness emerged with increasing age. Gender was an important explanatory factor of sleeping habits and sleep difficulties. In our study, the sleeping time of the pupils was in accordance with the common recommendations, and no differences were found between boys and girls.

All the pupils had a sufficient amount of physical activities in terms of the exercise recommendations. They participated regularly in physical exercises at school, in their spare time and in exercise clubs. The results support earlier studies by Fogelholm et al. (2007) and Opetusministeriö (2008).

The results of the study seem to be quite reliable. The questionnaire was pretested with 20 pupils aged 10-11 who did not participate in the study. Two of the researchers co-operated throughout the study. Co-operation has positive effects on the quality of a study (Soininen, 1995, 120). Our results also supported existing results in the literature. However, due to the small number of respondents the results cannot be generalized.

It is important to realize that the physical, mental and social dimensions of health are interconnected with each other. Health education should support pupils' holistic growth and development of health-promoting behaviour. Based on our results, the pupils follow the nutrition, sleeping and exercise recommendations well. The importance of breakfast and the school meal for concentration and feeling should be discussed more at school. The most important topics to be included in the curriculum and in the teaching, learning and studying processes of health education seem to be those which are especially related to mental and social welfare. In addition, the significance of rest and sleep for health should be emphasized. If it is an objective of health education that pupils have skills such as recognizing their abilities and reflecting on their own knowledge and attitudes, pupils should be allowed to participate not only in carrying out the processes in the lessons but also in the planning and evaluation of their studies. Development of health awareness should be based on conscious experiences, ideas, beliefs, and knowledge. In this connection, knowledge does not only mean facts and concepts but also understanding of phenomena and their relations, as – besides theoretical knowledge – pupils also construct new knowledge through action. Efficient health education also requires that parents participate and work together with the members of the school community. Thus the ability of pupils to make healthy selections, to care for their own health, and to take social relationships into account in everyday life will improve step by step.

EXPERT TEACHERS' TEACHING MODELS OF LIFE-CYCLE THINKING IN CHEMISTRY INSTRUCTION – A DESIGN RESEARCH

Marianne Juntunen[1] and Maija Aksela[1]
[1]The Unit of Chemistry Teacher Education, Department of Chemistry, University of Helsinki, Finland

Abstract: The aim of this design research is to improve the quality of teaching of life-cycle topics in chemistry instruction through in-service training. The novel course provided information on different aspects of life-cycle thinking in chemistry, and inquiry-based learning. The aim of this course is to support students' positive attitudes towards chemistry, and conservation of environment. The research questions in the first phase of this design research were: (i) what kind of teaching models do expert teachers from secondary and high school level develop during a short in-service training course related to life-cycle thinking in chemistry, and (ii) what kind of feedback do the trained teachers give on the usefulness of the course? As a result of this case study, the topics of teaching models developed by four trained expert teachers included: the life-cycle of cotton, water, and an optional subject generated from student interest. According to the teachers' feedback, this kind of environmental course was beneficial for them. The next phase of this design research is to study the implementation of the developed models in practice at school.

Keywords: design research, case study, in-service training, life-cycle thinking, inquiry-based learning

INTRODUCTION

Environmental aspects are more and more important in education of children and young people around the world. Teachers have requested improvements to the field of environmental teaching design and green chemistry (e.g. Taskinen, 2008; Lumivaara & Aksela, 2002; Feierabend, Jokmin & Eilks, 2011). Chemistry teachers have described that the teaching of environmental matters is currently more general than in-depth. They have also cited that the topics are taught with little relevance to the students' everyday life. One aim of Finland's curriculum in chemistry is to promote variable learning skills typical to science, and to identify the life-cycles of products and substances, and their importance to the environment and nature (Finnish National Board of Education, 2004). Also pupils' abilities to use chemistry knowledge in promoting health and sustainable development as a consumer, and in discussion and decision-making are evaluated (Finnish National Board of Education, 2003).

From chemical perspective, life-cycle thinking combines green chemistry and engineering. It is an approach that evaluates the environmental burden of a product, process or activity. By quantifying resource use and emissions, and assessing their health impacts, it is possible to find possibilities for improvements (Anastas & Lankey, 2000).

From educational perspective, life-cycle thinking is a socioscientific teaching approach.

The educational applications of it have not been studied earlier. In teaching, socioscientific issues focus on empowering the students to consider how science-based issues reflect moral, social and physical world around them (Zeidler, Sadler, Simmons & Howes, 2005). Like Marks and Eilks (2009) point out, by implementing various relevant and controversial socioscientific issues into science teaching, it is possible to provoke and allow open discussion and individual decision making processes. In practice, teaching methods may include e.g. learner centred instruction, cooperative learning, use of authentic media and controversial debate. The aims of socioscientific and critical approaches are to promote students' motivation, improve their attitude towards chemistry in general, and reach a broad range of educational goals in personal, cognitive and moral development (Zeidler et al., 2005; Marks & Eilks, 2009).

Many studies have highlighted an alarming decline of interest in key science subjects among young people in Europe (Rocard, Csermely, Jorde, Lenzen, Walberg-Henriksson & Hemmo, 2007). The attitudes of young people towards studying chemistry have changed to more negative also in Finland in the short run (e.g. Asunta, 2003).

Educational research points out the benefits of increasing inquiry-based teaching methods, as used in this in-service training. Inquiry-based education has been proven to support the young peoples' interest to study more science (Rocard et al., 2007; the Inter Academy Panel, 2010; Colburn, 2000). For students' motivation, it is likely important that chemistry education is closely related to their everyday life and surrounding society (Marks & Eilks, 2009; Rocard et al., 2007). By combining socioscientific issues, like life-cycle thinking, to inquiry-based learning methods, it is possible to support the pupils' interest and variable skills in science (Marks & Eilks, 2009).

METHODS

The aim of this design research was to improve the quality of the teaching of life-cycle topics in chemistry instruction through an in-service training course. The course is studied as a case study and it is the first phase of the design research (Edelson, 2002). It includes a theoretical problem analysis and an empirical problem analysis. The research questions were: (i) what kind of teaching models do expert teachers from secondary and high school level develop in a short in-service training course related to life-cycle thinking in chemistry, and (ii) what kind of feedback do the trained teachers give on the usefulness of the course?

In the theoretical problem analysis, Finnish chemistry textbooks and science curriculum were analyzed by content analysis (Tuomi & Sarajärvi, 2006). The words "life-cycle", "ecological pack bag", and "footprint" were searched from the curriculum and books, and classified according to their place in text, and picture, chart, or exercise setting. Secondly, the inquiry level of the exercises was evaluated as structured, guided or open inquiry (Colburn, 2000).

In empirical problem analysis, four expert chemistry teachers voluntarily attended an in-service training course, which was implemented in two parts (2 days + 2 days). The course included e.g. discussion about the possibilities of green chemistry as an answer to environmental crisis, information on different production processes with regard to pollution and consumption, introduction to inquiry-based education concept, green chemistry related school laboratory experiments, specialist lectures, and visits to waste water plant and green chemistry laboratory. After two course days and based on the discussed topics, teachers got a task to write an open, inquiry-based report. The aim was to improve their own teaching related to life-cycle thinking and inquiry-based learning. They created three “raw” teaching models that were collaboratively developed into more inquiry-based direction during the course with the other teachers and with few chemistry education researchers. A similar collaborative design of sociocritical chemistry teaching models has been described in participatory action research by Marks and Eilks (2009).

In empirical problem analysis, the focus was on three teaching models created by the in-service trained teachers. In content analysis, the models were classified according to whether they had already fulfilled the goals set to them. If not, the teachers collaboratively designed their models further. The goals of the model were similar to those of Marks and Eilks’s (2009). It should:
- use inquiry-based approach
- reveal the relevance of chemistry in environmental protection, as well as in political discussion and decision-making
- motivate and inspire the pupil to protect environment and study chemistry
- develop skills for cooperative studying, critical thinking, problem solving, communication, and evaluation.

A structured 5-point Likert feedback questionnaire of the Finnish National Board of Education was used to evaluate the teachers’ opinions after the course. The statements in the questionnaire included evaluation of course content, training methods, teachers' learning outcome, and lectures of the course topics given by specialists from various fields. To get a wider view on the teachers’ thoughts, also three open pre and post questions were asked: 1) Describe the concept “inquiry-based learning” in your own words? 2) What kind of factors are included in “life-cycle thinking”? 3) Give comments on the course, ideas and wishes.

RESULTS AND CONCLUSIONS

The research questions were answered by the following results. Four in-service trained expert chemistry teachers developed and tested three novel student-centered teaching models (see Table 1). The models combined life-cycle thinking and inquiry-based learning approach for secondary or high school purposes.

Table 1. Three teaching models created by the in-service trained teachers.

Teaching model	Goals of the model	Implemen-tation	Level
Life-cycle of an optional product	To investigate and analyze the life cycle of a product by using internet, experts’ help and peer review. Finally, a presentation of the project works.	2–3 students, 6 x 75 min	upper secondary or high school
Life-cycle of water	To investigate and analyze water cycle in nature and become familiar with (waste) water purification.	2–4 students, 4 x 45 min	high school
Life-cycle of cotton	To create an info table about the environmental effects of T-shirt production and usage.	2–4 students, 5 x 45 min	polytechnic (or high school)

The designed models discuss a life-cycle of cotton, water, and an optional subject. They are inquiry-based and student-centred. The students take responsibility for themselves and decide, what is important for them to investigate. Depending on the students' skill-level, the teaching models can be implemented as structured, guided, or open inquiry (Colburn, 2000).

The models use variable learning materials, methods, and ways of working including pair or small group work, and opponent review. This is similar to what is described by Marks and Eilks (2009). Only difference to their sociocritical teaching models is that "clarifying chemistry background in a laboratory environment" is almost absent in the presented models. As the time is limited in lessons, the trained teachers designed their models to emphasize students' question-making, cooperative information search, critical discussion, peer review, and presentation of the findings. They even suggested a conference-type gala evening to conclude the students' work.

Similarly as described by Kolsto (2011), socioscientific issues with different levels of complexity involve and develop different kind of competence. Also here, the trained teachers focused the evaluation of students' outcomes more on the research process than on the factual knowledge.

This type of in-service training course can be used to train more teachers. In the 5-point Likert feedback questionnaire, the teachers graded the course as good (4) or very good (5). They reported to recommend this type of a course to their colleagues. In the open questions, they described the course as "beneficial" and "giving new ideas". The analysis suggests that the trained teachers gained new competence to guide their students through the topics of life-cycle chemistry using inquiry-based methods of learning. Four teachers attended the prototype of the in-service training course. In a larger group, the teachers would benefit more from each other's knowledge and opinions.

In general, a design research produces a design solution that here are the three teaching models. Besides, it also generates knowledge about the design process and the domain itself. (Edelson, 2002) Thereby, the next step is to further develop a synthesis model of these and to study the developed models in practice at school (e.g. Marks & Eilks, 2009). After the course, the teachers are encouraged to test their novel teaching model in a school setting with their students. However, the teachers are still missing an inspiring in class introduction to the concept of life-cycle thinking with green chemistry examples (e.g. Anastas & Lankey, 2000). One possibility is to design it collaboratively with teachers or student teachers in the subsequent phases of the design research.

AN INVESTIGATION OF ENVIRONMENTAL RISK PERCEPTIONS OF PRIMARY AND SCIENCE PRE-SERVICE TEACHERS

Mustafa KAHYAOĞLU[1], M.İkbal YETİŞİR[2] and F.Kıyas BİREL[3]
[1]Siirt University Education Faculty, Turkey
[2] Ankara University Education Faculty, Turkey
[3]Dicle University Education Faculty, Turkey

Abstract: Environmental risk is a phenomenon arising either from natural or man-made reasons at local or global levels. Environmental risk perception, on the other hand, for the solution of environmental problems and reducing the risks threatening the environment is an important step to increase awareness of an individual and society. For this reason, exploring individuals' and society's environmental risk perception is important for environmental education. The main purpose of this study is to investigate the primary school teachers' perceptions of environmental risk. In addition, it also aims at finding out whether student teachers' perceptions of environmental risk change based on gender and according to program of study in which they were enrolled at the time of study. Research was carried out with 204 teachers enrolled both in Science Education and Elementary education program in Faculty of Education at Siirt University. Instrument for this study was originally developed by Slimak and Dietz (2006) and was translated into Turkish by Altunoğlu & Atav (2009) entitled as "Environmental Risk Perception Scale". In our study, the internal consistency Cronbach's alpha coefficient was found to be 0.89. Also, teacher candidates' perceptions of environmental risk were found to be moderate, and high awareness of environmental issues was identified.

Keywords: Environmental, education, perception, preservice teacher, risk

INTRODUCTION

Environmental problems could be defined as accumulation of factors detrimental to living organisms' living and behaving patterns. These are mostly man-made such as ozone depletion, air and water pollution, acid rains, global warming, excessive fertilization, pollution of rivers, deforestation, climate changes, greenhouse effect, and extinction of some species. Rapid spread in industrialization and consequent increase in people's living standards have also resulted in environmental problems we all likely have to encounter in our daily lives. Although scientists and environmentalists highlight the scale and intensity of environmental problems, there does not seem to be enough will on the people's part to confront these problems. According to Erten (2004) in today's world environmental problems cannot easily be solved by technology or new legislations but by changing people's perception of them. In this regard, Soran and et. al. (2000) suggests that environmental education should start at pre-school age for children, thereby making them aware of dangers posed by environmental disasters. Ayvaz (1998) also claims that there is a direct link between awareness for environment and getting ready for action to minimize the bad effects of environmental disasters. Consciousness for environmental issues can be wide-ranging, entailing the interplay between ecologically responsible people and high sensitivity to environmental problems. In this framework, we could summarize that there is a social aspect for solving environmental problems. The literature on environmental issues presents there is, albeit at different level, a growing concern among all walks of life in modern societies (Dunlap et. al. 2000; Slimak &

Dietz 2006; Beyhun et al.2007; Gürsoy et. al. 2008; Altunoğlu & Atav, 2009; Sam et.al. 2010).

According to Baldassare & Katz (1992), environmental risk perception plays a critical role for developing and enhancing consciousness for environmental issues. Environmental risk, when broadly defined, is a culmination of dangers arising either in the form of human or natural disasters. Environmental risk perception, on the other hand, could be stated as people’s subjective judgments of these problems (Anantho, 2008). The literature on environmental risk perception has been seeking answers on such questions like, why do some people put high priority on some problems over others? or why does the environmental risk perception change from person to person? The literature also show that people from their opinions on environmental issues from different standpoints. Techno scientific approach views environmental risk perception as concrete, easily defined and observable, measurable phenomenon (Mark et.al. 2008). Psychometric approach, though it accepts techno scientific approach’s principles, considers other factors influencing risk perception (Slimak & Dietz; 2006). Comprehensive person of model includes such psychological factors as adaptability, emotional stability, psychomotor aspects of people in their analysis of risk perception (Chauvin et.al., 2007). Socio-economic, demographic and religious factors have great influence over risk perception. (Stern et.al.1999). Lastly, the trend called ‘risk society’ in 1990s puts risk at the heart of social and historical factors influencing social structure in modern societies (Yalçınkaya & Özsoy; 2003).

A multitude of measurement tools have been developed to study individuals’ and society’s environmental risk perception some of them, and their results are shown in table-1. Different samples of environmental risk perception surveys conducted show that people conceive of environmental risks at various levels. According to Sam et al. (2010) study of university students on environmental risk perception and environmental attitudes, university students appear to demonstrate high levels of environmental risk perception, and the perception of environmental risk and environmental attitudes they report signals strong positive relationship. Altunoğlu & Atav (2009) have found that, in their study on secondary school students' perceptions of environmental risk, secondary school students' environmental awareness on the environmental risk perception is higher than average. Similarly, Gursoy et al (2008) in their study on mid-level municipal employees, state that environmental risk perception is high, awareness of environmental issues is even higher. However, the levels of public risk perception and risk characteristics that determine the environmental risks in relation to the society needed to be trained by health professionals. However Beyhun et al (2007) study on the medical school classes, environmental risk is found to be perceived less urgent by the medical students. Meydan et al. (2009) in their study on student teachers claim that while teachers identify the global climate changes, global warming, air and water pollution, water waste of industrialization on the environment as a threat , perceive consumption habits and the luxury of life as a problem, but they do not adequate awareness and sensitivity on the greenhouse effect, acid rain, ozone depletion and erosion. Environmental risk perception for individuals who are sensitive to the problems of the environment is very important in creating or strengthening of these behaviors. It is known that that low attention to environmental problems, as well as the environment caused by the false perception of risk is very problematic.

The main purpose of this study, primary preservice teachers and science preservice teachers is also to determine the perceptions of environmental risk, perceptions of environmental risk education program, and whether they differ in a meaningful way in terms of gender.

METHOD

Participants

The study was conducted in the spring of 2009-2010 academic year at Siirt University in Turkey. Participants were 204 preservice teachers who were attending at primary and science education departments education departments in faculty of education.

Data Collection and Analysis

A descriptive survey research design was used in this study. As a means of data collection; personal information forms developed by the researcher and environmental risk perception scale which is developed Slimak and Dietz (2006) and adapted into Turkish language by Altunoğlu and Atav (2009) was used. This scale aims to measure the environmental risk perceptions of preservice teachers. Confidence in environmental risk perception scale, the Cronbach alpha reliability coefficient was 0.89, high points indicate how high is perception of environmental risk of preservice teacher. Factor analysis of this scale consists of 4 factors, accounting for 57% of the total variance. The first factor in factor distribution of substances, "*Ecological Risks*" (Cronbach's alpha = 0.82), the second factor "*Chemical Waste Risk*" (Cronbach's alpha = 0.79), the third factor, "*Extinction Risk of Resources*" (Cronbach's alpha = 0.81) and the fourth factor is the "*Global Environmental Risks*" (Cronbach's alpha = 0.69), respectively. Ecological risks consist of the following: loss of wetlands, invasive species, genetically modified agricultural products, forest sector, the construction of dams, chemical pollution of inland waters, eutrophication. The risk of chemical waste encompasses hazardous waste, radiation, heavy metals, persistent organic compounds, sewage, pesticides. Risks of resources are sport fishing, commercial fishing, overgrazing and population growth. The risks of global warming are in the acid rain, greenhouse effect, ozone layer depletion substances and oil extraction. In our study, Cronbach's alpha reliability coefficient, 0.79 for *ecological risks*, *the risks of chemical waste* for the 0.75, 0.78 for *the risk of depletion of resources* and to *global environmental risks*, 0.77, respectively. Cronbach's alpha reliability coefficient of 0.89 was determined to be the value in the scale.

RESULTS

Table-1. Means and standard deviations of primary and science preservice teachers' environmental risk perceptions scores

	N	Minimum	Maximum	$\bar{X}$	SS
Science preservice teachers	51	3.30	4.96	4.15	.40
Primary preservice teachers	153	2.17	5.00	4.16	.59
Total	204	2.17	5.00	4.16	.55

As shown in Table-1 mean scores of primary preservice teacher and science preservice teachers' environmental risk perceptions are high level.

Table-2. Primary and science preservice teachers' perceptions of environmental risk ranking of the distribution of points

Science preservice teachers' perception of environmental risk	Ranking	$\bar{X}$	SS	Primary preservice teachers' perception of environmental risk	Ranking	$\bar{X}$	SS
Hazardous waste areas	1	4.72	.53	Greenhouse effect	1	4.65	.68
Greenhouse effect	2	4.68	.58	Radiation	2	4.63	.72
Acid rain	3	4.66	.74	Acid rain	3	4.58	.74

Persistent toxic organic compounds	4	4.66	.51	Persistent toxic organic compounds	4	4.56	.77
Radiation	5	4.62	.52	Ozone layer hole	5	4.48	.82
Ozone layer hole	6	4.58	.53	areas of hazardous waste	6	4.55	.87
Sewage	7	4.58	.60	sewage	7	4.37	.94
Heavy metals	8	4.41	.72	Heavy metals	8	4.37	.86
Chemical pollution of inland waters	9	4.35	.84	Chemical pollution of inland waters	9	4.32	.87
Invasive species	10	4.33	.86	Euthrophication	10	4.26	.89
Degradation of habitats	11	4.31	.81	GMO	11	4.26	1.06
GMO	12	4.29	.94	Loss of wetlands	12	4.19	1.04
Oil drilling	13	4.25	.95	Oil drilling	13	4.08	1.03
Euthrophication	14	4.23	.73	Invasive species	14	4.17	1.00
Loss of wetlands	15	4.19	.87	Degradation of habitats	15	4.13	1.05
Pesticides	16	3.98	.96	Population growth	16	4.02	1.19
deforestation	17	3.96	1.14	deforestation	17	4.01	1.11
Dam construction	18	3.84	.92	Pesticides	18	3.97	.97
Population growth	19	3.78	1.13	Dam construction	19	3.75	1.23
Overgrazing	20	3.29	1.20	Overgrazing	20	3.75	1.13
Sports fishing	21	3.23	1.14	Sports fishing	21	3.54	1.25
Commercial fishing	22	2.94	1.13	Commercial fishing	22	3.30	1.36

According to table-2 science preservice teachers see, as the most important top five, environmental risks of hazardous waste, the greenhouse effect, acid rain, persistent toxic organic compounds and radiation, while the perceptions primary preservice teachers can be ranked like this: greenhouse effect, radiation, acid rain, persistent toxic organic waste and ozone layer depletion. It can be said that primary preservice teachers and science preservice teachers perceived as the most significant environmental risks in a similar pattern. Primary preservice teacher and science preservice teachers see the following less threatening environmental risks starting with the least important concern: commercial fishing, sport hunting and over-grazing were found.

Table-3. Means and standard deviations of preservice teachers' environmental risk perceptions subscale scores

Environmental risk perception subscales	**N**	$\overline{X}$	**SS**
Global environmental pollutions risks	204	4.47	.63
Chemical waste risks	204	4.43	.54
Ecological risks	205	4.18	.61
Exhaustion of resources risks	204	3.57	.95

According to Table-3, preservice teachers' perceptions of environmental risk as part of the subscales of global environmental risks, the highest mean scores can be attributed to (4.47), chemical waste risks (4.43), and ecological risks (4.18) and risks of depletion of resources

(3.57) According to this, perception and awareness of the risks of global environmental pollutions risks of preservice teacher are higher than chemical waste risk, ecological risks and exhaustion of resources.

Table-4. t-test results of preservice teachers' environmental risk perceptions subscale according to gender

Environmental risk perception	Gender	N	$\bar{X}$	SS	t	p
Global environmental pollution risks	Female	99	4.54	.56	1.59	.113*
	Male	105	4.40	.65		
Chemical waste risks	Female	99	4.45	.51	.612	.541*
	Male	105	4.41	.57		
Ecological risk	Female	99	4.26	.55	1.74	.082*
	Male	105	4.10	.69		
Exhaustion of resources risk	Female	99	3.64	.93	1.01	.310*
	Male	105	3.50	.97		

* p> 0,05

There is a no significant difference between the preservice teachers' global environmental pollution, chemical waste, ecological risk and resources exhaustion of environmental risk perceptions subscales when we consider gender as shown in table-4 (p>0.05). This means female preservice teachers' global environmental pollution, chemical waste, ecological risk and resources exhaustion of environmental risk perceptions subscales are higher than male ones.

Table-5. t-test results of preservice teachers' environmental risk perceptions subscale according to departments

Environmental risk perception	departments	N	X	S	t	p
Global environmental risks	Primary	153	4.45	.65	-.990	.323*
	Science	51	4.54	.46		
Chemical waste risks	Primary	153	4.41	.58	-.974	.321*
	Science	51	4.50	.36		
Ecological risks	Primary	153	4.16	.67	-.663	.508*
	Science	51	4.23	.48		
Exhaustion of resources	Primary	153	3.65	.96	2.23	.026**
	Science	51	3.31	.91		

*p> 0.05; **p< 0.05

In this study, the mean scores received from the environmental risk perceptions subscales were evaluated according to preservice teachers' departments. The preservice teachers' mean scores perceptions of global environmental pollution risks (t= -.990; p=.323), perceptions of chemical waste risk (t=-.974; p=.321), perceptions of ecological risk (t= -.663; p=.508) didn't different according to department.

As seen in Table-5, science preservice teachers' perceptions of global environmental risks, risks of chemical waste and ecological risk are higher than those of the primary preservice teachers. To see whether any significant difference based on these two programs, namely, primary preservice teacher and science teachers' perception of global environmental risks, the risks of chemical waste, ecological risks and risks of depletion of resources, according to the independent sample t-test result was analyzed. As a result, no significant difference between primary and science preservice teachers' perception of global environmental risks (t_{202} = -,990, p> 0.05), the risks of chemical waste (t_{202} = -,974, p> 0.05) and ecological risk perception (t_{202}= -,663, p> 0.05) was found, while there was a difference for perception of depletion of natural resources (t_{202} = 2.23, p <0.05).

CONCLUSION AND DISCUSSION

As a result, this study tries to find out how primary and science preservice teachers environmental risks perceive. Prospective teachers of primary and science environmental risk perception show almost the same level. Primary and science preservice teachers' perceptions of environmental risks reveal the following risks as the most urgent ones: the greenhouse effect, hazardous waste sites, acid rain, persistent organic waste compounds, radiation and ozone layer depletion. Similar studies like the one done by Beyhun et al (2007) shows that the medical students perceive as the most significant environmental risks: stress and the ozone layer hole. Gursoy et al (2008) in their study of municipal employees, municipal employees perceive the environmental risks most important ones as hole in the ozone layer, air, water and nutrient pollution, global warming. Altunoğlu and Atav (2009) the most important risks perceived by secondary school students are the greenhouse effect, radiation and the ozone layer hole. Slimak and Dietz (2006) study identifies as the most important areas hazardous waste, persistent toxic organic compounds, sewage, heavy metals, radiation. Walsh-Daneshmand and MacLachlan (2000) study indicates hole in the ozone layer, smoking cigarettes in public places, factory-derived pollution and radioactive pollution.

In our study, the risks of global environmental risks and ecological risks of chemical waste and the depletion of resources have been found to be prominent than other risk perceptions. Accordingly, preservice teachers' perception global environmental risks and ecological risks of chemical waste occupy a more prominent place than depletion of resources According to the study by Ozdemir and Constructive (2010), the preservice teacher who teaches geography and physics show more sensitivity toward soil pollution than science preservice teachers who do not teach those courses. In our country there is not quite number of work on preservice teachers' perceptions of environmental risk. However, similar studies on the vast majority of high school and college students show that students are not informed about or have incomplete and inaccurate information on global warming, population growth, depletion of the ozone layer preservice teachers will train the next generations, therefore the environmental risk perception is crucial in the development of effective behaviors. Not just a theoretical approach but project-based, problem-solving skills by applying such methods are more needed in the duration of their university education to be aware of environmental risks and their solutions.

MAKING USE OF EDUCATIONAL RESEARCH IN THE PLANNING OF A NANOSCIENCE EXHIBITION

Antti Laherto[1]
[1]*University of Helsinki*

Abstract: Although museums and science centres have an explicit educational role, educational research is generally not taken into account in a systematic manner when designing exhibitions. Rather, the development of those learning environments tends to rely on the know-how of the staff. A consistent procedure of carrying out and reviewing science education research would complement that expertise and support the educational role of science exhibitions. This paper therefore suggests such research-based approach by adapting the Model of Educational Reconstruction for the purpose of exhibition development following the idea of the Model for Personal Awareness of Science and Technology. The former model serves as a general framework to involve analytical and empirical research in the development of learning environments, while the latter model provides a specific view of visitors' learning in interaction with exhibits. The paper shows how these constructivist models can be interconnected in order to apply educational research for improving the long term learning profit of exhibition visits. The idea is illustrated with an example concerning research-based planning of a nanoscience exhibition.

Keywords: educational reconstruction, informal learning, nanoscience, science centre exhibition, personal awareness of science and technology

INTRODUCTION

During the past few decades, the educational value of informal learning environments has been increasingly recognized. As learning is regarded as a learner-led and lifelong process, settings such as museums and science centres play an important role in complementing formal education and in contributing to scientific and technological literacy (Bybee, 2001). Indeed, museums have undergone a big shift in terms of their role and justification in society (Hooper-Greenhill, 1992; B. Lord, 2001). They are now considered primarily as educational institutions. Exhibitions are the main mode of communication in museums and science centres, and thereby also the main way for executing the educational function of those institutions (Allen, 2004; Hooper-Greenhill, 1994; B. Lord, 2001). While the process of exhibition development usually relies on museum staff's and other designers' know-how (cf. Mortensen, 2010; Schauble & Bartlett, 1997), many scholars have pointed out the need for complementing that expertise and making exhibition development more research-based (e.g. Allen, 2004; Grewcock, 2001; G. Lord, 2001; Schauble & Bartlett, 1997).

The studies that may be useful in science exhibition development include not only museum research but also the fields of research on science education. Duit (2007) distinguishes the domains of science education research as follows: (1) Analysis of content structure; (2) Research on teaching and learning; (3) Development and evaluation of instruction / instructional design; and (4) Research on curricular issues and science education policies. This paper suggests how findings from all the domains of science education research, together with findings of museum research, can be used during the process of exhibition development in order to support the educational function of these environments. After suggesting a generic model, an example on research-based development of a nanoscience exhibition is given.

The suggestions here mostly concern the first phase of the exhibition planning process, i.e. the development phase (G. Lord, 2001, p. 4). The next steps of the exhibition project, phases of design and implementation, are chiefly beyond the scope of this paper. That is why e.g. the aspects of exhibit design and usability – that are crucial in terms of visitor's experience during the visit – are not addressed in the following. The paper does not suggest a complete model for exhibition engineering which is a far more complicated process including a variety of important considerations beyond the educational research findings.

THEORETICAL BACKGROUND

Literature on museum learning includes a multitude of studies that examine how the characteristics of an exhibit influence visitors' interactions, but as such they do not, however, provide a prescriptive model for how to exactly use that knowledge in exhibition development. Thereby, some suggestions for formalising the process have been made (G. Lord, 2001; Mortensen, 2010; Schauble & Bartlett, 1997). The present study complements these formalisations by suggesting how exhibition development may be informed by educational research in a systematic manner.

For this purpose, the study adapts one of the design-oriented research approaches, the *Model of Educational Reconstruction* (MER) (Duit, Komorek, & Wilbers, 1997; Duit, 2007), for use in exhibition development. MER is a methodological framework that combines analytical and empirical educational research with development of practical educational solutions. The fundamental idea of the model is that the content structure for instruction cannot be taken directly from science content structure, but has to be specially (re)constructed by paying attention to the educational goals as well as students' cognitive and affective perspectives. MER has three components that closely interact with each other: 1) Analysis of content structure; 2) Research on teaching & learning (including investigations on learners' perspectives) and 3) Development of learning environment (Duit, 2007).

Since the nature of learning in informal settings is different from formal education (see e.g. Allen, 2004), MER has to be specified with a view of learning in a science centre, i.e. an interpretation of visitors' interaction with exhibits and the aims of the visit, in order to be used in exhibition development. The approach suggested in this study uses the *Model for Personal Awareness of Science and Technology* (PAST) (Gilbert & Stocklmayer, 2001; Stocklmayer & Gilbert, 2002) to deliver such view. The model for PAST has a personal constructivist perspective that is in line with the modern views of museum learning, where audience is no longer seen as an undifferentiated mass, "the general public" (Hooper-Greenhill, 1992). According to the model for PAST, interaction with an exhibit can induce *an experience in a* visitor, whose *PAST* can thereby develop and move closer to the *target*, i.e. the scientific, technological or socio-scientific ideas represented in the exhibition. However, a fruitful experience necessarily has to arouse *remindings,* i.e. draw on visitor's prior experiences (Afonso & Gilbert, 2006). The model for PAST also emphasises that the educational significance of an exhibition visit arises in the long term, and should not be considered in terms of immediate learning outcomes.

SUGGESTION FOR A PROCEDURE FOR USING EDUCATIONAL RESEARCH IN EXHIBITION DEVELOPMENT

In the approach suggested in the study, the challenge of exhibition development becomes a challenge of creating appropriate *experiences*, related to some aspect of the *target*, that are likely to arouse *remindings* in visitors and interact fruitfully with visitors' *PAST*. Each of these elements can be considered in the light of research findings. Such procedure for employing educational research in the different phases of exhibition development is outlined in Figure 1. The procedure is developed on the foundation of the basic Model of Educational Reconstruction (Duit, 2007, p. 6) and to some extent resembles the earlier practical applications of it (e.g. Duit, Komorek, & Wilbers, 1997).

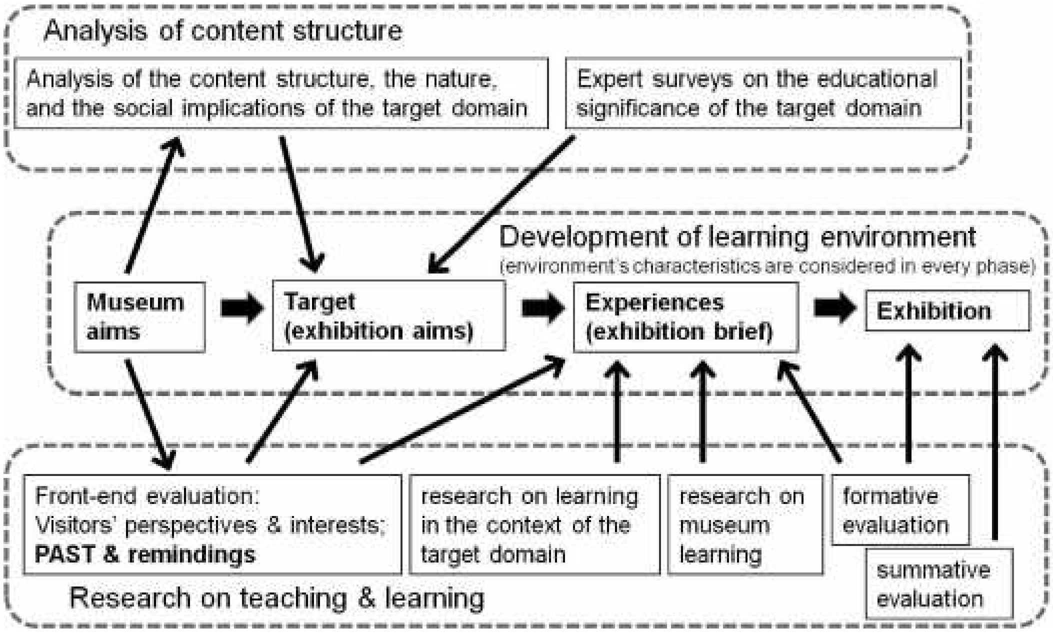

Figure 1. The suggested procedure for informing exhibition development through educational research.

The development phase of the exhibition planning process (G. Lord, 2001) can be roughly divided into four steps (Fig. 1): museum aims, exhibition aims, exhibition brief, and the actual exhibition (cf. Grewcock, 2001). Each of these steps can be informed with analytical and empirical studies carried out within the components 1 and 2 of MER. The *target* is defined on the basis of the general aims and characteristics of the museum, the analysis of content structure (drawing on literature on the nature and societal aspects of the content, and expert surveys) and the front-end evaluation of potential visitors' typical *PAST*s and *remindings* related to the *target*. The front-end evaluation also guides the development of the *exhibition brief*, describing the actual exhibits, by finding out fruitful contexts in which the *target* should be presented. Furthermore, this phase of exhibition development is supported by reviewing the literature on typical learning difficulties and conceptual challenges related to the *target*, as well as general literature on museum learning in order to find effective means of communication. After the exhibition brief the planning process continues to the design and implementation phases (G. Lord, 2001) during which the actual exhibition is created and evaluated. In the study, each of these ways for informing the exhibition development through research is discussed in detail in the context of the following example.

AN EXAMPLE: UTILISING RESEARCH FINDINGS IN THE DEVELOPMENT OF A NANOSCIENCE EXHIBITION

In order to illustrate the suggested approach, an example is provided on the use of educational research in the development of an exhibition on nanoscience. The example stems from a research project in the University of Helsinki, Finland, concerning nanoscience education. In the course of that research project an exhibition brief is being developed, hopefully to be later on implemented in a museum.

The process began by considering the general aims of the museum in question (see Fig. 1). On that basis, a tentative set of 'education for citizenship' -type aims were set for the nanoscience exhibition. They consisted of helping the visitors (1) to feel comfortable and competent with nanoscientific and nanotechnological matters and artefacts; (2) to follow the media discussion of the topics; and (3) to form informed opinions on social and ethical issues related to the fields. Such goals are broad enough to accommodate the visitors' personal needs, interests, and viewpoints in line with the idea of the model for PAST.

While contentual, curriculum-like learning goals do not fit an exhibition, the aforementioned aims must be broken down to a bit more specific aims in order to be usable in exhibition development. The planning team has to ponder what kind of knowledge of science and technology would, for instance, contribute to one's ability to make decisions on related issues. Such questions are constantly asked in science education research, and reviewing that literature can be used to choose content for informal settings as well. Hermeneutic-analytical studies on a specific field of science or technology, and analyses of its *educational significance* (Duit, 2007), can provide a good starting point for the exhibition development team. When laying the groundwork for the nanoscience exhibition, a review of the science and technology studies (STS) scrutinizing the field from philosophical and sociological viewpoints (e.g. Baird et al., 2004; Brune et al., 2006) was carried out (see Laherto, 2010). Furthermore, also empirical content-oriented studies may be used in defining the target of an exhibition (see Fig. 1). A growing number of expert surveys and Delphi studies have been published, analyzing the educational significance of many emerging fields of science and technology (for nanoscience, see Brune et al., 2006; Stevens, Sutherland & Krajcik, 2009). Also, surveys on science teachers may be useful since educators can be considered as experts in choosing content for science education. The nanoscience exhibition project applied some results of a survey on science teachers' views of the educational significance of nanoscale science (see Laherto, 2011a). All in all, the analysis of content structure for defining the target of the exhibition (Fig. 1) revealed not only the central scientific and technological ideas and concepts of nanoscience and nanotechnology (size-dependent properties, self-assembly, quantum effects, etc.), but also a number of educationally interesting features in the nature of these fields (interdisciplinarity, the 'technoscientific' character, distinctive roles of modeling and imaging), and in their interrelationships with society (potential benefits and risks), that are worth addressing in the exhibition.

Yet, at least equally important approach in defining the target of the exhibition is the front-end evaluation (Fig. 1). Visitors' perspectives are studied by reviewing pre-existing survey results or by conducting a new survey – preferably both of the ways should be used. The example project involved a review of polls and surveys on public's perceptions of nanoscience (see e.g. Crone, 2010). However, it is usually necessary to carry out a survey locally too, on the potential visitors of the museum in question. There are at least two alternative approaches. One is to survey a statistically meaningful sample of the whole target audience. Another approach is to conduct a small-sample interview or a focus group study in order to get a deeper insight (though not statistically significant) into the potential visitors' perspectives. In the nano-exhibition project, the latter approach was chosen. The results highlighted some fields of nanoscience and nanotechnology that the potential visitors may find especially interesting and relevant.

In the third phase, the *exhibition brief* (see Fig. 1), findings of that same visitor survey were utilized in order to find the typical misconceptions and learning difficulties which must be taken into account when designing the actual exhibits. The outcomes of the survey pointed out that, for instance, it is difficult to convey the correct epistemological ideas with the electron (or atomic force) microscope images widely used in nanoscience communication (Laherto, 2011b). The exhibition brief was also informed with a review of the educational research literature on teaching and learning of nanoscience. Several studies have, for example, shown that people of all ages have major problems in understanding the nanoscale (e.g. Castellini et al., 2007; Tretter, Jones, Andre, Negishi, & Minogue, 2006), but scale conception can be supported by teaching the continuum of scales, using relative comparisons instead of absolute sizes, providing size landmarks, and promoting proportional reasoning (Tretter, 2008). Such educational strategies were found to be appropriate for exhibitions too, and thereby such exhibits were included in the exhibition brief.

Furthermore, the procedure involved a review of research findings on museum learning (Fig. 1). While Brazilian exhibition *NanoAventura*, for example, solved the museographic challenge of displaying nano-objects in an exhibition by using computer games and virtual representations (Murriello, Contier & Knobel, 2006), the U.S. exhibition *It's a Nanoworld* employed concrete macroscopic models and analogies (Batt, Waldron, & Trautmann, 2004). For the exhibition brief, both types of exhibits were chosen. The literature review increased an understanding of the advantages and risks of different museographic approaches, thereby making it possible to use those approaches deliberately.

CONCLUSION

Hooper-Greenhill (1994) has argued that museums and science centres have failed in implementing their educational function. While this paper does not claim to provide a solution to this alleged problem, it does suggest how utilising findings from educational research in the development of science exhibitions might improve the educational potential of those learning environments. The paper proposes a generic model for museum professionals' use, and illustrates the model by providing an example on the development of a nanoscience exhibition. As the example discusses a research project instead of a typical exhibition project in a museum, it must be acknowledged that usually museums do not have much time and resources to engage in research during exhibition development. Even if the suggested model could not be used in its entirety, it still may be helpful in raising discussion on the need and the various possibilities of utilizing educational research in exhibition development.

As a personal constructivist model, PAST is line with the epistemological and learning-theoretical position of MER. Together they provide an approach for developing an exhibition with epistemological and learning-theoretical orientation that follows the lines of "the constructivist museum" suggested by Hein (1998, 155-179). MER provides a specification of different domains of literature and types of research that can be utilised in the process, whereas PAST specifies the purposes of those studies in terms of supporting visitors' *experiences* with the exhibits.

THE CONTRIBUTIONS OF SYSTEMIC THOUGHT TO ENVIRONMENTAL AND HEALTH EDUCATION

Christine Marques Palácios[1], Rossano André Dal-Farra[1] and Marlise Geller[1]

Universidade Luterana do Brasil

Abstract: The growing problems observed nowadays concerning sciences, technology, health and environment require far-reaching approaches that often need to transcend the teaching practices commonly adopted in formal education and that bring an effective contribution to scientific literacy. In this scenario, the present study addresses the contributions of systemic thought to the pedagogical practices that require the construction of links between different fields of knowledge, especially concerning Health and Environmental Education. As a whole, the results obtained show that the activities help pupils think over environmental issues due to the development of systemic though directed to the themes related to their communities. The results also show the importance of pedagogical practices that advocate the construction of contents as a wide network of themes whose directions make it necessary to utilize new approaches to the teaching of Sciences.

Keywords: Scientific literacy; Environmental education; Health education; Systemic thought, Elementary school.

INTRODUCTION

Finding efficient solutions for the problems observed in learning essentially requires the understanding of the dynamic of the interconnection between different classes of knowledge, especially the interdisciplinary aspects inherent to Environmental Education. For this reason, in order to include complex themes in elementary schools — like the use of agrochemicals, the consumerism observed in contemporary societies, alcoholism, and the outbreaks of epidemics like that of dengue — more comprehensive approaches that address several interconnected issues observed in the school community and its surrounding settings are required.

In this context, the present study analyzes the contributions of systemic thought to different approaches in the teaching of Sciences that include diversified pedagogical practices. With this in mind, the present paper reports the results of the investigations conducted with elementary school pupils on different relevant themes for contemporary education.

The debate between vitalists, who advocated the existence of a vital principle in living beings, and the mechanicists, was the fertile ground for theories called organismic and that hypothesized that organisms enjoy the ability to integrate their component parts and their functions. In this sense, Ludwig von Bertallanffy (1901 – 1972) aggregated the fundamental laws of chemistry and physics to philosophical questions, proposing a generalized version of the classical theory of thermodynamics that could be valid for closed systems as well as for open systems. Open systems were then used to explain the properties of living organisms as well as the processes that occur in systems formed by several animal and plant species, in the ecological relationships they have with one another. Due to the fact that open systems absorb energy, these systems are inclined to present negative entropy in a state of dynamic equilibrium that may lead to an increase in complexity (WECKOWICZ, 1989). Bertalanfyy (1975) defines system as a set of interrelated units.

In this perspective, when using systemic thought we are employing an approach that considers the whole without reducing it to its smaller parts. Therefore, the properties of the parts can only be understood based on the organization of the whole.

In this context, Morin describes systemic and complex thought as:

A key-thought, since it is built on the knowledge of the complex meaning of the word ‘system’. A system is not only formed by its parts; it has qualities, properties so-called emerging and that do not exist in each of its parts; in other words, the whole is larger than the sum of its parts. However, some qualities or properties of the parts are often likewise inhibited by the whole: thus it may also account for less than the sum of its parts.

In a scenario where the school is seen as a space of excellence for the diffusion of relevant knowledge, the discussion of themes about environmental issues includes the construction of interconnections between the different instances of knowledge that exist in society so as to establish prolific ways to the development of the community against the demands that continually emerge nowadays.

In this perspective, the environmental issue and the interfaces it has with health are examples of this complexity, especially considering the growing modifications that we observe in the environment built based on the growing presence of the human being in this context based on technology.

METHODOLOGY

This research was developed with a qualitative approach involving three different groups. The first one involved 10 7th grade pupils studying “consumer behavior”. The second one with 60 8th grade pupils studying the “dengue control” and the last one with 96 8th grade pupils discussing the “consumption of alcoholic beverages”.

This study had three stages:

- pretest – the preliminary data were collected obtaining the important subjects related to the used themes;

- practice activity – the main concepts were presented using dialogic explanation considering the knowledge of the students, discussing the interrelated between the different themes of the contemporaneity.

- posttest – additional data were obtained aiming to analyze the knowledge of students about the themes after dialogic explanations.

THE RESULTS

Based on the discussions about the dengue epidemic held with elementary school pupils (EINSFELD, 2009), the relevance of pedagogical practices that take into account the pupils’ previous knowledge gathered with the help of dengue control campaigns became apparent. Also, the need to implement actions in the community based on the effective role played by schools as protagonists of the diffusion of knowledge that add decisively to the fight against this disease was also observed, since the changes in the environment introduced by society represent one of the key aspects in the detection of outbreaks of the disease and in the establishment of prevention strategies.

In a study carried out on the theme “consumption” (PALÁCIOS, 2008), an approach was conducted that initially was associated to waste and garbage by pupils. Pupils demonstrated a relevant shift from essentially fragmented analyses towards a more systemic view of the themes analyzed, with allusions to environmental issues — more specifically to garbage — as well as the consequences of this aspect to the hydrological networks of cities. Additionally, direct references were made as to the impacts of the consumerism process to the health of citizens. This trend to broaden the spectrum of analyses and to conduct more in-depth reflections about the role of the human being in the environment represents the most important objective of the activity. This trend makes the actions developed in schools and directed to the promotion of citizenship and to the betterment of society more effective.

Another relevant theme is the consumption of alcoholic beverages, which demands specific actions in schools towards a better understanding of the ways to address the issue in a more effective way so as to alert pupils about the risks of alcoholism. The preliminary results afford to state that the theme was associated to there distinct spheres: (i) the consumption of alcoholic beverages in parties; (ii) the health problems associated (especially liver conditions); and (iii) the traffic accidents as a negative outcome of the consumption of alcoholic beverages. The answers revealed that youngsters have the hindsight of some relevant topics on the theme concerning health, and it was possible to observe that there is a need to enlarge the discussion on this theme so as do cover less commonly discussed consequences of alcohol to some systems of the organism as well as the social issues involved, aiming to promote debate. It was possible to observe, based on the activities carried out, that the youngsters were conscious of the risk of drinking, though this does not mean that such aspect changes their behaviors in everyday life. Therefore, it was revealed that this theme is very vast, and that is raises the curiosity of youngsters and that should be routinely addressed as important in scientific literacy. Also, the results confirm the advantages of systemic approaches that address the relationship between the different organism systems and, more broadly, the relationships between an individual’s values, habits of consumption and the consequences to the health system and the traffic and violence issues observed in our cities (DAL-FARRA, 2009).

Based on the development of pedagogical practices of this nature, the insertion of important contemporary themes based on systemic approaches affords the contextualization of themes without leaving behind fundamental conceptual aspects in the teaching of Sciences.

The quantitative results obtained were discussed on Dal-Farra et al. (2009), Einsfeld et al. (2009) and Palácios (2008).

FINAL CONSIDERATIONS

The activities conducted contribute to the pupils’ reflections about education, health and environment issues, due to the development of knowledge of thought directed to the themes related to the respective communities and global questions, and point to the importance of pedagogical practices that value the construction of contents on a systemic approach. The pupils´s reflections appointed to interrelationships between the themes, including environment, health and society in the context in which they live, connected with global issues relevant in contemporary contexts.

The results indicate also that teachers need to know the information transmitted in media about the themes of their disciplines to construct the strategies for teaching.

The studies conducted with elementary school pupils afforded to observe that acting based on a systemic approach to Environmental Education and Health Education affords to analyze and act more widely in terms of the possibilities to consider the insertion of the human being in this context. In this sense, the approaches conducted in the perspective of systemic thought contribute to the articulation of themes in different disciplines when we try to understand the multiple relationships, the randomness and the interdependence between the processes studied both in the context of Natural Sciences and in its interface with health issues and social aspects.

LEARNING SCIENCE IN INTERACTION WITH THE EXHIBIT IN A MUSEUM OF NATURAL HISTORY

Jesús Piqueras[1] *and Karim M. Hamza*[1]
[1]Department of Mathematics and Science Education, Stockholm University, Sweden

Abstract: In this paper we present a study of science learning in a museum of natural history. We videotaped an educational activity where three teacher students study an exhibit with preserved animals, showing an eagle eating the carrion of a roe deer. There were also a pair of crows; one of them staying at a prudent distance from the eagle, whereas the other pinches the eagle's tail. Through a practical epistemologies analysis, we studied student's meaning making through the development of their discourse in encounter with the exhibit. The conversation generated by the activity is represented as sequence steps associated to six different themes. The theme concerning the behavior of the crows was one the themes where the students appeared to have gone furthest in the process of meaning making of the exhibit; they were able to provide a plausible explanation of the scene in terms of ecological relationships. In contrast, the theme concerning the carrion appeared to be considerably more difficult to make sense of; the students were able to fill several gaps concerning the identification of the carrion by distinguishing anatomical details; however, they could not fill the gaps concerning the absence of parts of the roe deer. The previous analysis of the conversation represents a description of learning from the point of view of the students; however it was possible to describe which aspects of the exhibit were noticed, what was easy to make meaning of and what remained unexplained.

Keywords: Museum, practical epistemologies, student teachers.

INTRODUCTION

For many years, museums have been known as environments that encourage informal learning experiences of individuals, families, and school children. In the field of museum education studies, an extensive research has been conducted with family visitors using a socio-cultural perspective (Leinhardt, Crowley & Knutson 2002). However sociocultural studies focusing on the relationship between informal learning, communication, and the purposes of the exhibit are unusual (Rennie, 2007). In this paper we present a discursive analysis of students' learning in encounters with an exhibit at a museum of natural history. The outcome of the analysis is then used to assess the relevance of the learning taking place, compared with the purpose of the exhibit.

Analysis of practical epistemologies

We used in this study an analysis of practical epistemologies. This method, which allows a description of meaning making in socially shared practices, has been used to analyze learning in school practices (Hamza & Wickman, 2008; Jakobson & Wickman, 2007; Lidar, Lundqvist, & Östman, 2006) and informal learning settings (Piqueras, Hamza & Edvall 2008). A practical epistemology analysis is an analysis of the actions taken by the participants of an activity as they engage in coping with what occurs in the situation. To analyze these actions on a discursive level, Wickman and Östman (2002) introduced four concepts: *encounter, gap, relation,* and *stand fast*. *Encounters* occur basically between persons and between persons and artifacts. As an activity proceeds, the participants notice *gaps* as a result of such encounters with other persons or artifacts. To fill a gap, new *relations* need to be established to what *stands fast*. Stand fast is defined as those words and utterances that are used by the interlocutors without questioning.

METHODS

The data presented in this study comes from a teaching activity of the educational program at the Museum of Natural History in Stockholm. The activity selected for our study utilizes a variety of exhibits with preserved animals in scenes that reproduce their natural environments. In small groups, and without the help of exhibition texts, the participants study the exhibits and try to make sense of different animals' behaviour, ecological processes, and biological interactions. The data presented here comes from three teacher students' encounter with an exhibit showing an eagle eating the carrion of a roe deer in a snowy landscape (Figure 1).

Figure 1. The exhibit

In the exhibit there are also a pair of crows, one of them staying at a prudent distance from the eagle whereas the other pinches the eagle's tail-feathers. The main purpose of the exhibit is to show the co-operating behavior of the crows to steal food from the eagle, but also to challenge the imagination of the visitors by placing details and clues in the scene (i.e. the missing head of the roe deer). The students' conversation was audio and videotaped and transcribed verbatim. The transcription was coded by marking *stand fast*, *encounters*, *gaps*, and *relations* in accordance with the analysis of practical epistemologies. After that, the conversation was divided into a series of steps, where the criteria for segmentation were the themes discussed during the conversation. Hence, a new step was initiated when the students began a new theme or switched from one theme to another.

RESULTS

The conversation generated in the encounter with the exhibit is presented here as a sequence of twelve chronological steps associated to six different themes (Figure 2). Here we present the initial part of first step and theme ("The behaviour of the crows"; Figure 2), showing how the practical epistemology analysis has been used throughout the conversation:

T: The crow…that he dares to pinch…at the tail's feathers.
E: Yes! Exactly!
E: That the crow dares to go so close!
T: Yes.
T: He [crow] is really pinching him [eagle]!
E: That was cocky!
T: Yes, indeed! Furthermore, I thought…It must be so that…They're carrion eaters!

E: Mm.
T: So they dare because they're surely starving.
E: Would he eat the crow?
T: I wonder about it ...They don't.
E: Well…it's not generally in the menu, but…
T: Well…I thought that…the little I know about vultures…
E: Yes…
T: There are no animals that eat vultures…They're at the bottom of the food chain, I think so…I'm not completely sure…I just believe so.

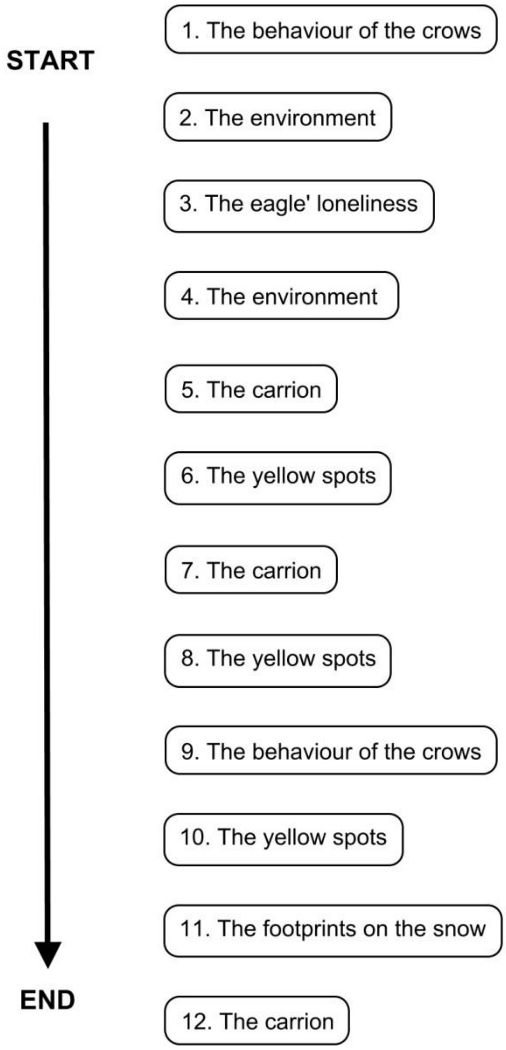

Figure 2. The path of the conversation represented as as a sequence of twelve chronological steps associated to six different themes.

Two gaps were noticed in this theme. The first gap concerned the behavior of the crows and especially how they could be so close to an apparently dangerous, much larger animal. The gap was filled with relations to the crows being carrion eaters and starving. The second gap concerned whether the crows could be a potential prey to the eagle. They filled this gap in a consequent way with the former relation about carrion eaters by establishing a relation to vultures and their foraging behavior. We may also note that several words stand fast to the students, that is, words that they used without questioning. These words, for example crow, vulture, starve, they, are used as starting points for establishing new relations to fill the noticed gaps.

The theme concerning the behavior of the crows (steps 1 and 9) was one the themes where the students appeared to have gone furthest in the process of meaning making of the exhibit; they were able to provide a plausible explanation of the scene in terms of ecological relationships between the birds. In contrast, the theme concerning the carrion appeared to be considerably more difficult to make sense of, that is, gaps lingered in several occasions. In the different steps where they talked about the carrion, the students noticed rather different gaps, focusing on the species (step 5), anatomical details and missing parts of the animal (step 7, 12).

Step 5:

T: Look at the animal [pointing out the carrion].

A: Ah…

T: I get curious…what kind of carrion is it?

E: I wonder…is it a lemm.. [lemming]?…what can it be?

T: Yes! I think so, it doesn't looks like an animal from the archipelago.

Step 7:

T: I wonder which part of the animal…if you think…
E: He [the eagle] has eaten the front part [of the carrion].
A: These are rib bones.
E: Mm.
A: There goes the oesophagus.
E: Exactly, some kind of throat.
T: He's eaten the whole head!

Step 12:

A: The question is if he [the eagle] can eat the head by himself.
T: No, that's right, the head's gone…and the legs! Where are they? I'm curious about what kind of animal it is.

The students were able to fill several gaps concerning the identification of the carrion by distinguishing anatomical details. However, they could not fill the gaps concerning the absence of the head and legs; these gaps lingered from step 7 and remained unfilled in step 12.

DISCUSSION

Analyzing students' conversation in this way makes it possible to view their learning as a journey, where the different themes represent alternatives path for the direction of the learning process. For this particular group of students, the six different themes represent those particular paths that they happened to explore in the encounter with the exhibit. The previous analysis of the conversation represents a description of learning from the point of view of the students. However it was also possible to describe which aspects of the exhibit were noticed, what was easy to make meaning of and what remained unexplained. We can conclude, that the students succeeded in finding an interpretation of the scene using a set of ecological explanation, but the carrion was a problematical part in the exhibit for the students. Similar analyses of other dioramas and activities can be performed, either by a researcher, a teacher, or a museum educator, for purposes of research, teaching, or, indeed, fine-tuning of museum exhibits.

PRIMARY SCHOOLS TEACHERS' CONCEPTIONS OF ENVIRONMENT. A COMPARISON BETWEEN AUSTRALIA AND FRANCE.

Frances Quinn[1] *and Pierre Clément*[2]
[1]University of New England, Armidale, Australia: fquinn@une.edu.au
[2]S2HEP, University Lyon 1, Université de Lyon, France Pierre.Clement@univ-lyon1.fr

Abstract: Both Australia and France are similarly developed countries with comparable egalitarian societies but differ in some issues such as energy generation, agricultural and mining history, GMO cultivation, immigration. Both countries have implemented Education for a Sustainable Development (ESD) in their respective education systems. This paper explore primary teachers' conceptions of the environment, and how these relate to the broader national socio-scientific differences.

Using the questionnaire of the European research project Biohead-Citizen, we compared, by multivariate analyses, conceptions of 98 Australian and 272 French primary school teachers.

The Australian teachers' conceptions significantly differ from those of French teachers, mainly being more pro-GMO, more anthropocentric and believing more that some animals can feel happiness. The most anthropocentric and pro-GMO conceptions are correlated with more belief in God, practising religion, and trusting more in private than in public institutions, for schools, for health services and pensions. They also agree more with the propositions: *"It is for biological reasons that women more often than men take care of housekeeping"*, ***"****Ethnic groups are genetically different and that is why some are superior to others"* and ***"****There are too many foreigners in my country: the government should limit immigration"*.

Some hypotheses are proposed to interpret these differences, such as resistance to GMOs in France and Australia's immigration history. The greater endorsement in the Australian sample of values against equality between men and women, or among ethnic groups, is more difficult to explain, but may possibly relate to education or to characteristics of the local sociopolitical contexts.

Keywords: Education for Sustainable Development – Teachers – Environment – Values – Human rights –

INTRODUCTION

Australia and France differ in relation to some socio-scientific issues likely to be associated with differences in environmental and socio-political views. For example, Australia was the last country to ratify the Kyoto protocol, is the world's largest coal exporter, and in contrast to France generates no nuclear power. Both countries have a strong agricultural sector, with

Australia having rapidly cleared much of its native vegetation for agriculture and mining. Although GMO cultivation (of maize) has been banned in France, GM canola has just been introduced to cultivation in Australia. Australia has seen rapid large scale immigration since colonisation by Europeans only 223 years ago and currently 25% of the Australian population is foreign-born in comparison to 8.9% of the French population (OECD 2010). The gender gap in unpaid work is larger in Australia than France (Craig & Mullen 2010).

Education for Sustainable Development (ESD) is well implemented in the school curricula of the two countries. Australia has a very strong policy framework for ESD – although the extent to which this is implemented by schools is variable and arguably threatened by recent moves to national high-stakes literacy and numeracy testing. Environmental Education for Sustainability policy in Australia is also, on the face of it, more focused on values than in France (*http://www.curriculum.edu.au/values*). In France, Environmental Education has mainly been developed since the 90s, becoming in 2004 Environmental Education "to" and then "for" Sustainable Development, and ESD ("Education au Développement Durable") since 2007. In France as well as in Australia, the best examples of ESD are found in Primary Schools, where the same teacher can encompass all the dimensions of ESD, and there is more possibility of interdisciplinarity, and pedagogical innovations, than in the more tightly circumscribed secondary school systems.

RESEARCH QUESTIONS

In consequence, the present work aims to explore differences in Australian and French primary schools teachers' perceptions of nature, the environment and environmental education. Specifically we are investigating:

- their ethics and values relating to the utilization and/or preservation of the environment (Wiseman & Bogner 2003), corresponding to anthropocentric and / or ecocentric values;
- their opinions about genetically modified organisms (GMOs) and their use;
- their opinions about the ability of all animals to feel or not feel happiness;
- if the teachers' conceptions differ significantly according to variables such as gender, age, level of instruction, religion;
- whether there are correlations between the teachers' conceptions of environment and their socio-political and religious opinions, and their conceptions related to human rights and equality.

METHODS

We used the questionnaire constructed for the Biohead-Citizen research project (2004-2008), where most of the questions are focused on possible interactions between scientific knowledge and values (Clément & Carvalho, 2007). Examples of questions will be given below with the results. Each teacher filled out the questionnaire in a totally anonymous context. The sample comprises 98 in-service and pre-service primary school teachers in Australia (New South Wales), and 272 in France (Rhône-Alpes and Languedoc-Roussillon). The data were analysed by multivariate analyses (Munoz et *al.* 2009, with the free software "R" and the collaboration of the statistician Charline Laurent).

MAIN RESULTS

A PCA (Principal Components Analysis), as well as a Hierarchical Ascendant Classification, defines 4 categories of conceptions of environment:

1 – A pole more focused on utilization of resources, with an anthropocentric ethic, and more acceptance of GMOs.

2 – An opposite pole more focused on preservation of environment, with an ecocentric ethic, and more reticence against GMOs.

Inside these two poles, there are two groups of conceptions, which differ according to whether teachers think that animals such as frogs, snails or flies can feel happiness or not.

A Between Analysis, completed by a randomisation test (Monte-Carlo type), shows that Australian teachers' conceptions significantly differ from those of French teachers ($p<0.001$), mainly being more pro-GMO for the four questions related to GMO (e.g. A12 & A39: table 1), more anthropocentric (e.g. A32: table 1) and believing more that animals such as frogs and snails can feel happy (e.g., A29: table 1). A somewhat larger proportion of Australian than French teachers think that Environmental Education should be more focused on providing knowledge than developing responsible behaviour (17.3% *vs.* 5.5%).

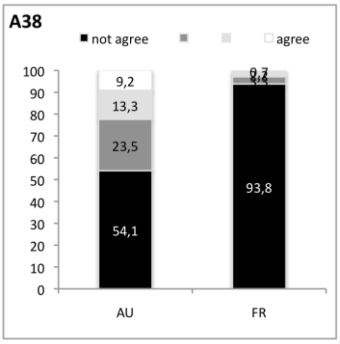
	Country	I don't agree			I agree
A12 – *"Genetically modified plants will help to reduce famine in the world".*	*Australia*	14.3%	27.6%	37.8%	20.4%
	France	36.4%	39%	20.6%	4%
A39 – "*Genetically modified plants are good for the environment because their cultivation will reduce the use of chemical pesticides (e.g. insecticides, herbicides)".*	*Australia*	16.3%	35.7%	35.7%	12.2%
	France	40.4%	39%	16.9%	3.7%
A32 – *"Humans have the right to change nature as they see fit".*	*Australia*	65.3%	22.4%	9.2%	3.1%
	France	91.2%	6.2%	1.5%	1.1%
A29 – *"Frogs are able to feel happiness".*	*Australia*	15.3%	29.6%	28.6%	26.5%
	France	39.3%	27.6%	22.1%	11%

Table 1 *- Answers of the 98 Australian teachers and 272 French teachers to some of the propositions of the questionnaire.*

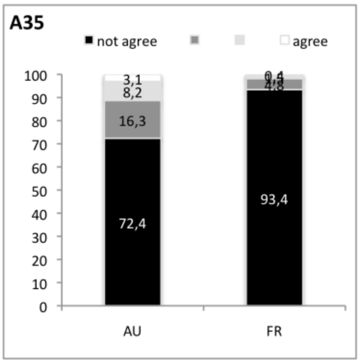
A Co-Inertia Analysis crossing the PCA from the variables Environment with a PCA from the socio-political and religious opinions shows that the most anthropocentric and pro-GMO conceptions are correlated with more believing in God, practising religion, and trusting more in private than in public institutions, for schools, for health services and pensions; and that these positions are more frequent in Australia than in France.

Another Co-Inertia Analysis crossing the PCA from the variables Environment with a PCA from the variables "human rights", shows a significant correlation: the teachers with the most anthropocentric and pro-GMO conceptions, also agree more often, for example, with the propositions A38 *("It is for biological reasons that women more often than men take care of housekeeping"*), A35 (*"Ethnic groups are genetically different and that is why some are superior to others"*) and A26 (*"There are too many foreigners in my country: the government should limit immigration"*): figure 1. That means that in Australia somewhat more teachers than in France wish to limit immigration (A26) and justify some inequality between men and women (A38) or between ethnic groups (A35) on biological grounds.

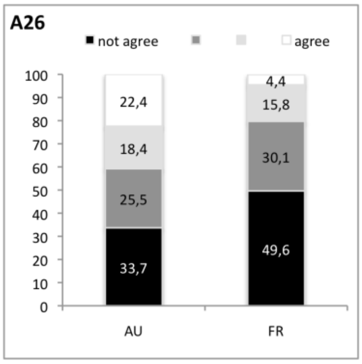
There are no significant differences among teachers' conceptions related to most of the other known parameters (gender, level of instruction, religion), except a little effect of age linked to the knowledge tested by item A49 – *"If a person eats genetically modified plants, his/her genes can be modified"*. The younger the teachers, (in both Australia and France) the more they disagree with this proposition.



A38 – "It is for biological reasons that women more often than men take care of housekeeping"



A35 – "Ethnic groups are genetically different and that is why some are superior to others"



A26 – "There are too many foreigners in my country: the government should limit immigration"

***Figure 1** - Answers of the 98 Australian teachers (AU) and of the 272 French teachers (FR) to the above propositions (in black: "I don't agree", in white: "I agree")*

DISCUSSION

Although the differences between Australian and French teachers are quite small, when compared to other countries in the world (see Clément & Caravita in this symposium, with the comparison between 24 countries), they are significant and raise several issues.

The finding that Australian primary teachers have significantly greater anthropocentric views with associated environmental utilisation ethic and acceptance of GMOs is likely to reflect broader national cultural differences outlined earlier in this paper, perhaps related to the relatively recent and lucrative history of utilisation of land for agriculture and mining in Australia. While GMOs are contentious in Australia, they are still being cultivated and there does not seem to have been the same widespread public opposition to the extent that has been experienced in France.

The Australian teachers' greater opposition to immigration may relate to the much higher proportion of immigrants in the Australian population and current concerns and media coverage about the arrival of 'illegal immigrants" and long standing fears of being "swamped by Asians".

More surprising is the greater number of conceptions in Australia justifying inequalities between men and women, and between ethnic groups on biological grounds. This raises the question whether this is a lack of biological knowledge, or also a justification of ideological positions on gender roles.

That fewer Australian than French teachers see Environmental Education as about developing responsible behaviour also signals a mismatch between the explicitly action-and behaviour-oriented EE policies in Australia and what is happening in Australian classrooms.

Abstract: The debate on healthy eating habits has been integrating many activities, inside and outside schools. The main professionals involved with this subject at schools are the science teachers, even though "health" is a transversal theme in Brazilian schools according to the National Curricular Parameters. The objective of the present study is to identify, within scientific publications, intersections between science education and health education in Brazilian schools amid the food and nutrition theme. In analyzing these papers, a focus upon teachers as the main knowledge transmitters was perceived, highlighting the necessity to enhance their knowledge on food and nutrition. It is important to signalize that teacher's contributions towards food and nutrition education in schools could involve a lot more. Teachers have the means to enrich the actual knowledge construction on this theme, to discuss the concepts of healthy eating habits, as well as the ways to analyze and understand their meanings and better forms of accepting them, or not. The presence of transdisciplinary views becomes fundamental especially when scientific concepts are involved. Nowadays it is not possible to talk about health whilst disregarding scientific knowledge and, on the other hand, science education constitutes an important field to be considered when health education activities are planned, especially at schools.

Keywords: food and nutrition education; science education; health education; transdisciplinarity; complexity.

INTRODUCTION

Presently, the debate on healthy eating habits has been integrating many activities, inside and outside schools. This demands efforts from different areas of knowledge and creates needs to deal with complex issues.

The Brazilian Ministry of Health has been working on the regulation of the food trade in schools with the objective of reducing the supply of unhealthy foods. Furthermore, there are recommendations from several governmental sectors concerning children's and teenager's eating habits with a focus upon the school environment. This concern can be observed within the proposals in the National Curriculum Parameters (PCNs) and the National School Feeding Programme (PNAE) from the Ministry of Education; the Ministry of Social Development and Fight against Hunger; the Food and Nutrition Security Policy and Health Promoting Schools from the Ministry of Health and the Interministerial Ordinance nº 1010/2006 a joint action from the Ministry of Health and of Education (Bezerra, 2009; Ribeiro & Caniné, 2007).

The National School Curriculum Parameters contribute to this issue by establishing health as a transversal theme that should be introduced in all subjects with different emphasis and in educational activities within the Brazilian schools. One of the objectives is that students start to value and adopt healthier eating habits as one of the basic aspects of well-being, and are able to act responsibly in relation to their own health and that of the community. This includes watchfulness over their eating habits. One of the great challenges for public schools, in this respect, is to create and maintain a connection between the PCNs and the National School Feeding Programme. Increasing attention has been drawn to PNAE because it is the most long-lasting and extensive enterprise in this context. It has also been undergoing changes in order to adopt educational actions and promote healthy eating habits with a transversal perspective in schools. The Health Promoting Schools initiative must be recognized for its understanding of health education with a holistic view and the suggestion of using participative methodologies for the creation of healthy environments and health service provisions. And finally, the Interministerial Ordinance nº 1.010/2006 establishes guidelines for the promotion of healthy eating habits within public and private schools and reinforces and extends the orientations of the PCNs. In this way, the complexity of the issue at hand is well acknowledged and suggestions for its incorporation within school curriculum have been made. The suggestions are based on integrating themes concerning eating habits in all of the study areas and providing day-to-day experiences in school, with a need for transversal propositions.

Changes in eating habits involve a complex phenomenon (Fischler, 1995) associating education with health sustenance, among other aspects. Thus, food and nutrition education require sectors and professionals from different areas of knowledge. This theme is a converging point between science education and health education, considering that it is an object of study in both areas. The former due to the understanding that science must be a part of general education so that all citizens may comprehend “the most general, positive and problematic implications” of what is defined as the “society of knowledge” and, in this case, its association with human being’s eating behavior (Schwartzman & Christophe, 2009). And in health education, because food and nutrition education fulfills what the World Health Organization proposed by dealing with “social factors that affect health, dealing with the ways in which different aspects of health and well-being are socially constructed”. Moreover, it includes “liberating pedagogical proposals, committed to the development of solidarity and citizenship, directing itself to actions with the purpose of improving the quality of life and of promoting mankind” (Schall & Struchiner, 2010). Although the possibilities for contributions in both fields of knowledge and the need for interdisciplinary and transversal approaches for the theme are recognized, this is not a reality within formal education. The introduction of food and nutrition education usually happens via science education due to its affinity to the curriculum and the teachers of this area. However, these teachers most commonly do not received training in the area of food and nutrition and therefore broach the theme superficially, giving out isolated information that falls short of the basic nutritional orientations (Souza, 2008). The same may occur with those who have the scientific knowledge within this theme, but have not been prepared to perform pedagogical interventions in schools.

In seeking elements that may expand this discussion, the objective of the present study is to identify, within scientific publications, intersections between science education and health education in Brazilian schools amid the food and nutrition theme.

METHODOLOGICAL PROCEDURES

A bibliographic survey was carried out in the *Scielo* database, within the title and the abstract fields, with the keywords “food and school”; “food and education”; “nutrition and school”; “nutrition and education”; “nutrition and science”; “food and science”. The search cumulated in 30, 40, 10, 28, 17 and 7 results for each keyword combination, respectively.

After a process of selection 12 papers published in Brazil, in the last 10 years (1999-2009), were included in this article. The selection criteria were articles related to food and nutrition themes within basic education.

RESULTS AND DISCUSSION

Were analyzed four papers related to topic of teachers training: Davanço *et al* (2004); Bizzo and Leder (2005), Schmitz *et al.* (2008) and Castro *et al* (2007). The other eight papers were analyzed in a previous study (Rangel & Fonseca, 2010).

The investigation carried out by Davanço *et al* (2004), aimed at evaluating the knowledge of teachers who had and those who had not been exposed to an educational programme. They considered that the exposed teachers were better prepared conceptually and were more aware of the roles of teachers and the school when it came to transforming reality.

Schmitz *et al.* (2008) also suggested a methodology for an educational programme to train preschool and elementary teachers and school cafeteria owners. They analyzed the participants knowledge on food and nutrition after and before the course. The conclusion was that the methodology helped expand knowledge amongst teachers and cafeteria owners, highlighting the school as a prime space for promoting healthy eating habits.

Broadening the focus to public polices, Bizzo and Leder (2005) proposed to include nutrition education programmes as a transversal themes in the National Curricular Parameters for Brazilian Elementary Schooling (PCN). These authors pointed out the necessity to adjust the nutrition undergraduate courses, to model and understand the construction and change in food habits within the school context, and to integrate this theme with other actions and interventions. These notes signalize an initial change in food and nutrition education views in schools, making it possible to think about an expansion of the concepts involved.

Finally, in the study developed by Castro *et al* (2007) there was an expressive participation of different school actors (elementary teachers, primary healthcare professionals, school cooks and adolescents) in testing an educational methodology for the promotion of healthy diets, adopting cooking as its structural axis. It was a theoretical and methodological innovation in the area, including concepts that had not yet been explored in this area, such as: “health promotion precepts, a critical approach to health education, the human right to adequate food, food and nutrition security and reflections about food culture in the contemporary context”.

Among these researches, eight papers were analyzed in a previous article (Rangel and Fonseca, 2010), indicating a relevant convergence between science education and health education. In these studies, it was possible to identify the transmission of scientific concepts as the main manner of conducting the health education interventions. It is important to highlight that most of these researches were carried out by health professionals, especially dieticians, and published in health journals. A similar conclusion was obtained by Silva and Fonseca (2009) that did not identify an explicit pedagogical intention in most of the food and nutrition education studies analyzed. When evident, the traditional theoretical and methodological views on education were predominant, with a main focus on knowledge transmission.

In understanding transdisciplinarity as a way to construct the unity of knowledge, considering the complexity (Nicolescu, 1999; Giotto, 2004), the need to interrelate knowledge in different research fields is strongly signalized, bringing to the discussions concerning food and nutrition some considerations from the area of science education. In order for this to become possible, the challenge to integrate health professionals and education professionals must be overcome. This challenge was also put in evidence by Boog (2009), who indicated this necessity as a means to enrich the Brazilian National School Feeding Program, which is managed by health professionals. Teachers do not recognize this program as an opportunity for pedagogical action because they do not participate in the decisions within it. Thus, the urge for investing in educational projects that involve a diversity of professionals is brought to the surface, in order for eating habits in school to become an possibility for learning and producing knowledge (Costa *et al*, 2001).

CONCLUSIONS AND IMPLICATIONS

In analyzing these papers, a focus upon teachers as the main knowledge transmitters was perceived, highlighting the necessity to enhance their knowledge on food and nutrition. It is important to signalize that the teachers' contributions towards food and nutrition education in schools could involve a lot more. Teachers have the means to enrich the actual knowledge construction on this theme, to discuss the concepts of healthy eating habits, as well as the ways to analyze and understand their meanings and better forms of accepting them, or not.

The presence of transdisciplinary views becomes fundamental especially when scientific concepts are involved. Nowadays it is not possible to talk about health whilst disregarding scientific knowledge and, on the other hand, science education constitutes an important field to be considered when health education activities are planned, especially at schools.

This way, socio-scientific issues could be one of the forms to integrate food and nutrition education with the knowledge enrolled in the different subjects at schools. It is a complex theme that involves concepts within the natural sciences, social and human sciences, environment and sustainable development, ethics, and many other areas of scientific and non scientific knowledge.

ENVIRONMENTAL EDUCATION AND CLIMATE CHANGE: POSSIBILITIES OF LEARNING THROUGH A GAME

Rosana Louro Ferreira Silva[1], *Simone Rodrigues de Freitas*[1], *Laury Amaral Lyers*[1], *Juscemácia Nascimento Araújo*[1]
[1]Universidade Federal do ABC – Brasil

INTRODUCTION

The Climate Change issue achieved projection in media and society, particularly after February 2007, with the publication of the forth Intergovernmental Panel Climate Change report containing predictions about the global warming issue, considering its causes mostly because of anthropogenic actions. The environmental education aims to forming critical citizens and that they participate individually or collectively of the problem solving in its social and environmental context.

Since elementary school, the content related to environmental issues should be discussed such as GCCs and their effects, searching for a comprehensive understanding of the social environmental issue and how it interferes in our daily routine, bringing the issue of climate changes to the classroom.

Since 1990 many countries have implemented investigations with the aim of collecting how the population in general or specific groups understand the climate changes and the related politics. Cartea (2008) coordinated the surveys of people's perception about the theme in Spain, having the following focus of analysis: the level of climate change identification as a problem; the valorization of its potential as a threaten; the deepness and scientific adjustment of information and the citizen's knowledge about climate changes; the sources of information access about the theme; the predisposition and the daily practices related to the reduction of greenhouse gases. It is also relevant to elicit the importance of knowing what the population in Brazil understands about this phenomenon considering they have been exposed to lots of media information.

To approach this polemical issue in the classroom and discuss these conflicts, we have built a game as an educational tool. The use of games in schools is one of the various resources to be used in discussion and understanding of contents in a more interactive way between students and teacher.

This work has as aims: to identify the elementary and high school students and teachers' conceptions regarding the theme; to produce material that would enable the pedagogical transpositions of the main scientific and social aspects related to the climate changes theme; to do workshop with the game in state schools searching for an integral view of the issue; identify the students learning aspects in relation to the theme after game interaction.

METHODOLOGY

To identify the representations related to the theme, we have developed an exploratory study through questionnaires, which aimed to identify if the person had already heard of the theme, where and the three first words that are associated with the expression climate global changes. The data collect tool was applied with 52 teachers of state schools and with 259 students of a state school of Santo André city, São Paulo, Brazil. From those data and theoretical references, the main conceptual contents were thought to be incorporated in the pedagogical material produced and in the proposals of discussions to be created from it.

The game was used in a state school workshop in November 2010, with 29 high school students in an average group of 4 people. After finishing the game we applied a questionnaire per group, searching for the identification of perceptions about the theme after the interactions presented by the game.

Evaluation of the target audience perception and production of the game

According to the survey all teachers had already heard of the theme and 31 students did not know anything about it. The teachers have as main source of information about the theme the television, the newspaper and the radio. The students have pointed out television, followed by the school and then newspapers and the Internet. Cartea data (2008) have also confirmed the use of media to spread information and masse access to technologies of information in great scale. In table 1, it is possible to evaluate the main representations about climate change of state school teachers and elementary/high school students:

Table 1 - Main representations about climate change of state school teachers and elementary/high school students

Associated words	**State school teachers**	**Elementary and high school students**
Global warming	-	78
Pollution	9	72
Heat	2	48
Melting/ Glaciers	10	26
Rain/ Flooding	6	46
Deforestation	5	44
Catastrophes/chaos /death	12	6
Greenhouse Effect	3	35
Cold	-	24
Action/habits/attitudes	20	1
Man /Anthropogenic	3	7
Ozone layer	8	2
Natural resources	2	13
Air / Atmosphere	-	12
Species extinctions	1	4
Snow/ Snow storm	-	10
Disasters /suffering	-	10
Burnings	2	7
Consumption	2	-
Protection/prevention/ sustentability	7	1
Garbage/ recycling	2	5
Carbonic gas/carbon dioxide	2	2
Education	4	2
Others	24	68

From data exposed in the previous table, it was possible to observe that this public has various interpretations of the phenomenon. Besides the information expressed in the figure, many other words were quoted only or two once and grouped in as “others”. It is pointed out that important aspects associated to the causes were quoted only a couple of times such as carbon dioxide, burnings and consumption. These superficial perceptions were also identified by Cartea (2008), indicating that the understanding has scientific and social politics gaps, thus not establishing a clear relation between the identified problem and the individual and collective responsibilities. The wrong relation with other environmental problems, such as ozone layer has also been showed by Rye *et al.* (1997) and Leandrini & Motokane (2009). Rye *et al.* (1997) emphasizes the need for instructional materials that help students differentiate which are the environmental problems.

It is observed that, in a general way, the words chosen by students express more numerously the consequences brought by climate changes than the causes, what has indicated us how important is to deepen the issues linked to the causes in the game. With those results and after theoretical deepening of the theme, the first prototype of an interdisciplinary pedagogical game on environmental education was developed for elementary and high school students, considering the following objectives: to handle situations and environmental issues related to global climate changes in a playful way; to relate the phenomenon with the daily routine of people and with different school contents; to offer possibilities of dialog before and after the game to work with the construction of consistent argumentations to position face to environmental issues; to develop skills to take actions of group participation in environmental problems, considering the regional particularities.

Having it in mind, a game of strategy was created using 20 cards with attributes of attack (causes, consequences and vulnerabilities) and 20 defensive (adaptation and mitigation) where each card has a meaning about climate changes besides 8 scenario cards representing regional Brazilian particularities. During the game, students looked for strategies to minimize the effects of global climate change in different scenarios.

In the workshop, students participated actively during the game and pointed out the following words as main ones: Greenhouse Effect, Pollution, Preservation, Biodiversity, Environmental Damage, Humanity, Burning, Recycling and Drought. The main actions students judged as minimizing factors of climate changes were: Preservation, Renewable development, Water preservation, Recycling, Biodiversity protection, Awareness, Environmental education, Planting and Replanting, Ecosystem protection, Forest recovering. We noted that more relevant new words were then learned.

CONCLUSIONS

After the game an oriented debate was mediated by the teacher who commented on and discussed with students the cause and mitigation of climate changes making a relation to what they saw in the cards and in the dynamic of the game. This was only the first workshop and others have been already planned to happen with the use of the material, from where we will bring more data to be analyzed. The material was designed to contribute with the inclusion of scientific knowledge about the theme, thus agreeing with Jiménez-Alexandre & Pereiro-Munoz (2002) that the use of conceptual knowledge, besides valuable it is necessary to understand the environmental issue, evaluating the possibilities for problem solution. The spreading of scientific knowledge and social and cultural order should reach the society and one of the ways is the environmental education through interactive materials that challenge the thinking and propose an investigative, participative and critical attitude.

TALKING SCIENCE: THE POPULAR ASTRONOMY OF CAMILLE FLAMMARION

Silvania Sousa do Nascimento[1]
[1]Faculdade de Educação – UFMG, Brazil
silnascimento@ufmg.br

Abstract: In scientific practice, there is no image by image. The image is still regarded as a process, the result of a theory or reasoning or a model representation. This article will introduce the discussion on the functioning of images in a popularization science work. We analyze the fifth edition the "Astronomy Popular" of Camille Flammarion. In this study we have taken the discourse functioning concepts proposed by Michel Foucault to analyze one semiotic system. In conclusion the study indicates a functioning of illustration and a demonstration of the evidence "do science" in this work.

Keywords: Camille Flammarion, the popularization of science, the discourse functioning, popular astronomy.

INTRODUCTION

Image in science is an association among a technical process, a referent, a phenomenon or an object that one wants to observe or represent, as well as a scientific model. Without these associations, an image in science is just a visual element, a characteristic which marks the memory. It may be a summary of an equation, a mathematical or physical concept or even the creation of lines and colors of a mathematical model. According to Sicard (1997), these images have two iconic paradigms: the first, similar to photographic, a tool captures a fraction of real object, while the second captures a diagram of operation, punctuates what must be seen. The images in scientific research apparently belong to the second paradigm, nonetheless the science popularization should be working more with the first one. It is this assumption which directs our work to investigate the functioning of the images included in a science popularization text.

The images in sciences to Latour (1997) are often "technical images", the result of an "regard orchestrated" by artifacts or theories. The image capture, however, is not enough for science. Robert Hooke and Antonie van Leeuwenhoek, through the microscope which was built in the seventeenth century, observed the plant cells. Only a century later, the cell theory could give a meaning to this observation.

Astronomy has a pioneering role in the development of images in sciences. The introduction of the telescope, according to Bennett (2007), has transformed the instruments of astronomical observation in the seventeenth-century. Until 1609, before the construction of the astronomical telescope of Galilee, astronomers with only the power of their eyes and looking at a small fraction of the electromagnetic spectrum started the adventure of sciences with the image in meticulous drawings which were the instruments of their arguments.

The images produced by science have become more and more complex in the extent that technology has the interaction with possible differentiated levels of energy in production. The new instruments: an electron microscope, a positron camera or a system of satellite-tracking, on the other hand, have lost the dialog with the human dimension. In this context, I will discuss, in seeking to query its pragmatic functioning within science popularization discourse, all contained in the 1955 Nicolas Camille Flammarion fifth edition of "Popular Astronomy”.

THE IMAGE IN DIALOG WITH A TEXT

When we talk about images inserted in sciences text, two natures emerge. The first nature of the image is the reflection on a mirrored surface, and the second nature of the illustration is the representation pictorial, which indicates what seems to be seen. I will consider Michel Foucault’s definition (2000) of discursive procedures group which coordinates the discourse order. Such works differentiate the penetration of subjects in the discourse products. The image is an important element in all languages: natural, mathematics, iconic, graphics among other things and, it may be considered a component of a communicational act where social actors build and share a universe of meaning.

To consume the communication act, the interlocutors are legitimate as communicating subjects who share intentions, purposes, intersubjectivites and ways of expression adjusted to the communicative situation (Nascimento, 2007).

In the study that we propose in this article, we analyze a general public book, which we can characterize as a science popularization work. The studies on science popularization texts, developed by Daniel Jacobi (1998), indicate a dynamic of writing around the concepts and the scientific terms which are employed for the circulation of scientific knowledge outside from their production and validation sphere.

THE POPULAR ASTRONOMY OF CAMILLE FLAMMARION

For Carle and Guédon (1988), science popularization, non-formal or informal education composed by a nomenclature, is still subject of controversy, but these authors suppose that we are talking about the promotion of public access to knowledge and to scientific and technological information by means of mechanisms of differentiated schooling. The astronomer Nicolas Camille Flammarion (1842-1924) has devoted his life to the disclosure of astronomical research. Its main publication, "Popular Astronomy", was published in 1879. His work includes books, directories and journal articles and, in 1882, he founded the Popular Astronomy magazine, a monthly bulletin which were broadly disseminated.

For Jeanneret (1994), Flammarion participates in a "extension program" committed "to say the reality" by proposing moving away from a theoretical discourse which characterizes the scientific language. Popular Astronomy presents very rich and some colored pages and it is a continuous text, cut by chapters with attractive titles, for example, the Earth in the sky. Eventually, the title is accompanied by a brief indication of the covered subjects: how Earth turns on itself and around the Sun... Each illustration has a title, which sometimes, is reported in the text. Before it, there is a text to read in its entirety, similar to other texts about the disclosure of time (JEANNERET, 1994: 256).

In all the six books, as well as on the astronomy´s instruments annex directed to amateurs astronomers, we find 819 images numbered, two celestial charts, tables with astronomical data and an index. Most of these images (607 out of 819) are photographs with illustrative function surrounded by Jacobi´s framework. There are also celestial and land charts (28), systems of graphs (155 tables, graphs and diagrams) and schemes (29). The presentation of each book is almost always preceded by a colorful image, being all the other photographs in black and white. The intention of the popularization without trivializing science is reached from restatements of scientific discourse considering the first discourse. The science popularization discourse, with the restatements which are characteristics, is well marked, for example, by the complete explanation of elements which make up the project.

> Camille Flammarion aimait dire qu'il faut vulgariser la science sans la rendre vulgaire. Telle est la formule qu'il a appliquée dans cette Astronomie Populaire, dont le succès immense a contribué à répandre les connaissances astronomiques et a suscité de nombreuses vocation d'astronomes.Mais cet ouvrage irremplaçable exigeait aujourd'hui une refonte complète: sans en altérer le plan, il convenait d'y introduire les étonnates découvertes de la science contemporaine, et notamment un tableau de l'univers sidéral d'une telle ampleur que l'imagination bardie de Flammarion lui-même n'arait jamais osé le concevoir. Heureusement, l'éducation scientifique du public actuel l'a préparé à recevoir l'enseignement direct des faits et à goûter la poésie des spectacles grandioses qu'un abondante illustration photographique met ici sous ses yeux. (1955:p.3 griffin our)

In this book, the discourse, in general, is restated by the explanation in different languages, for example, the photography below 351 (p.249) which illustrates the nuclear reactions represents a descriptive form (1 Carbone^{12} + Proton = Azote^{13} + Energy) and an explanatory text.

IMPLICATIONS FOR THE SCIENCE POPULARIZATION

The images can be thought, in the case of Flammarion's science popularization work, in a dynamic among instruments, real object and its representation. This "real object" is an ideal shared by the French popular education program, by the time it approached sciences speech and scientific education, movement which still been observed in the 20th century, in the constitution of scientific culture associations (NASCIMENTO, 1999). The use of photographic images can be interpreted as this "explanation of real".

The interest on the image in this work can be attributed to its evidence value. The development of photography, in the 19th century beyond being an element of proof, in the science popularization discourse brings the traces of the object observed involved by delight and emotion. There is in this edition, also an attention to show images of scientists in pictures, paintings, engravings, and in scenes of using instruments. The illustration functioning favors the sensational aerial photo images, as well as inaccessible spaces: polar landscapes, Earth or global images, images of the limits of the universe, among others. These works still can be observed today, in the election science popularization images in this science area. A relationship ever investigates how these images can be found in other sciences writing traditions, and in the science teaching. In this study, however, we introduce this theme for the discussion toward opening other possibilities for future analyzes.

URBAN AND RURAL PRIMARY SCHOOL PUPIL'S CONCEPTIONS ABOUT THE RESPIRATORY SYSTEM AND SMOKING

Rosa Branca Tracana[12], Isabel Varanda[2], Sara Viveiros[2], Graça S. Carvalho[2]

Abstrat: An important objective of primary school teaching is to make children learn scientific contents and for this teachers must know their pupils' previous ideas in order to provoke effective conceptual changes. We analysed primary school pupils' conceptions and their learning difficulties by carrying out a cross-sectional study. Conceptions of respiration and smoking of young pupils (5/6 to 8/9 year old) were analysed before the first formal teaching of the topic and we followed their conceptual change immediately after teaching and one year after. We focused on the anatomo-physiology of the respiratory tract as well as on the unhealthy effects of smoking. The aim was to identify not only patterns of children's previous ideas about breathing and smoking unhealthy effects but also epistemological and didactical obstacles to learning.
Several patterns on the passage of tobacco in the smoker's body were created from children before teaching. Significant differences ($p<0.05$) between urban and rural schools as well as between year sub-samples of either urban or rural schools were found. After formal teaching, about 90% of 3rd and 4th year pupils represented the correct anatomo-physiology of the respiratory tract ($p<0.05$). However no significant differences regarding smoking effects were found ($p>0.05$). The use of these patterns of children's previous ideas about breathing and smoking may be relevant for teachers to use them in the process of pupils' conceptual change.

Keywords: Primary school, Respiratory System, Smoking, Urban and rural pupils.

INTRODUCTION

Children coming to primary school have their own conceptions that have been built from their daily life and some personal learning from parents' education, children's books, TV and other media. An important objective of primary school teaching is to make children learn scientific contents and for this teachers must know their pupils' previous ideas in order to provoke effective conceptual changes (Driver *et al.*, 1989; Pozo & Crespo, 1998; Canavarro, 1999; Giordan, 1999; De Vecchi & Giordan, 2002). Two types of pupils' learning obstacles have been identified: (i) epistemological obstacles, related to children's conceptions gained from their everyday life, and (ii) didactical obstacles, related to inadequate formal teaching (Clément 1994, 2003). Previous reports have described pupils' conceptions on digestion from their drawings (Carey 1985, Turner 1997, Giordan, 1999, Teixeira 2000, Psarros and Stavridou 2001, De Vecchi & Giordan, 2002, Reiss *et al*. 2002, Author, 2004) but on the respiratory system little has been investigated. In the present study we analysed primary school pupils' conceptions and their learning difficulties by carrying out a cross-sectional study. Conceptions of respiration and smoking of young pupils (5/6 to 8/9 year old) were analysed before the first formal teaching of the topic and we followed their conceptual change immediately after teaching and one year after. We focused on the anatomo-physiology of the respiratory tract as well as on the unhealthy effects of smoking. The aim was to identify not only patterns of children's previous ideas about breathing and smoking unhealthy effects but also epistemological and didactical obstacles to learning.

METHODOLOGY

In this study the data collection instruments included a questionnaire, which consists of an iconic part and a text. In this collection, we applied the technique of expression in the form of design because the children, in this age group, express better their ideas and their knowledge through the iconic representation (Giordan e de Vecchi, 1988). The design avoids the embarrassment of the child and the design is an alternative way for students who have difficulty expressing their ideas verbally (Rennies e Jarvis, 1995). The use of drawings is a technique that identifies the students' conceptions.
This is a transversal study applied to pupils of the four earlier school years of primary school (5/6 up to 8/9 years old). The teaching of the respiratory tract (and the others human systems) occurs at the 3rd year in the Portuguese curriculum. The schools were from urban and rural areas of Braga District, 191 and 201 children, respectively. We applied a short questionnaire, interviewed the children, and also analysed their textbooks. Children from the 3rd year were questioned one week after the teaching. They had to answer to the questions by making drawings as well as writing captions and any notes they thought could explain their drawings. Younger children of the first and second school year (5-7 years old) were helped by the researcher in the writing.

The questionnaire was composed of 5 simple questions:

i) Draw where the breathing air goes in your body.
ii) Look at your drawing and explain where the air goes in your body.
iii) Draw where the tobacco goes in the body of a smoker.
iv) Look at your drawing and explain where the tobacco goes in the smoker's body
v) What are the tobacco effects?

Categories were created from the children's drawings and writings (Marshall & Rossman, 1999; Bardin, 2000). Each drawing and writing was then allocated to a given category and data were treated by using the Qui-square method at the significance of 95%. The Statistical Package for the Social Sciences (SPSS) program was used.

RESULTS AND DISCUSSION

Several *drawing categories* about the passage of tobacco in the smoker's body (**question *i***) were created out of the drawing of 1st and 2nd year children, before teaching (Fig.1). A larger variety of drawing categories could be found in urban (Fig. 2a) than in rural (Fig. 2b) schools. Some 1st and 2nd year pupils drew only one lung ("L1") or two lungs ("L2", Fig.1a) with no connecting tube; one or two lungs with a single tube ("L1t/L2t", Fig.1b) and there were cases of two lungs with two tubes in parallel ("L2L", Fig.1c). The correct representation of two lungs with two tubes joining a single tube (L2T) (often darkened, highlighting the tobacco injury, "L2Td", Fig.1d) were also present in a proportion around 20% before teaching, in both urban and rural schools (Fig.2).

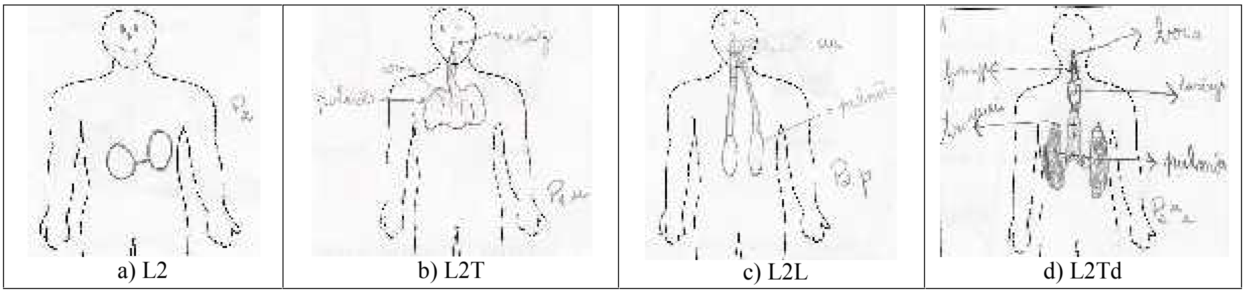

Figure 1: Examples of drawings of four categories found in pupils' drawings before (a to c) and after (d) teaching.

After the formal education the category "Lungs" increases in the 3rd year to 92% and there is a regression in this category, the following year (83%) in favour of other minor responses, namely the category "not known" where 13% of the students proved difficult to explain and name the organs through which the tobacco smoke, confounding them with organs of other biological systems. We can then infer that after a year of these learning, students in fourth grade did not retain concepts and knowledge about the category "Lungs".

Significant differences ($p<0.05$) between urban and rural schools as well as between year sub-samples of either urban or rural schools were found (Fig.2). After formal teaching, about 90% of 3rd and 4th year pupils represented two lungs with two tubes joining a single tube ("L2T"), where above 20% of urban (Fig.2a) and above 10% of rural (Fig.2b) pupils darkened the lungs, "L2Td", highlighting the smoking harm. The formal teaching in this case is clearly evident, which is confirmed by statistical analysis, $p<0.05$.

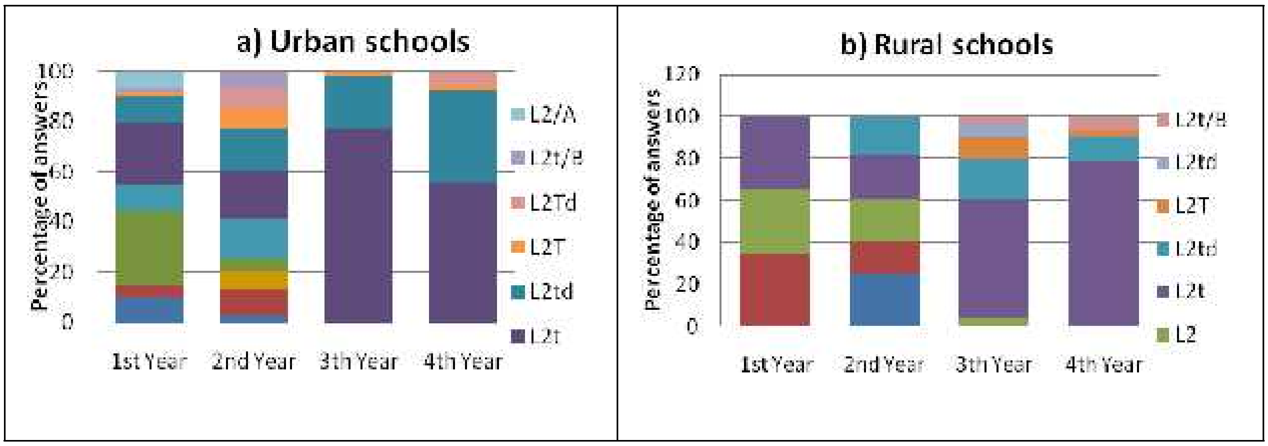

Figure 2: Categories frequencies on the tobacco passage through the body in urban (a) and rural (b) schools.
P<0.05 between urban and rural samples, and between sub-samples of urban and rural samples.

The *writing categories* "Disease/Lungs" and "Disease/Death" concerning tobacco smoking (**question *v***) were the most frequent ones in both urban and rural children (Fig. 3). No significant differences were found among samples ($p>0.05$): neither between urban and rural samples nor between year sub-samples within each urban and rural sample. These results show the breathe teaching at year 3 caused no significant effects on children's conceptions regarding the effects of smoking. However the category "Disease/Lungs" tend to decrease from the 1st to the 4th year in the urban school (Fig 3a) in contrast to the rural schools which tended to increase slightly (Fig.3b), though this being not significant at the level of 95%.

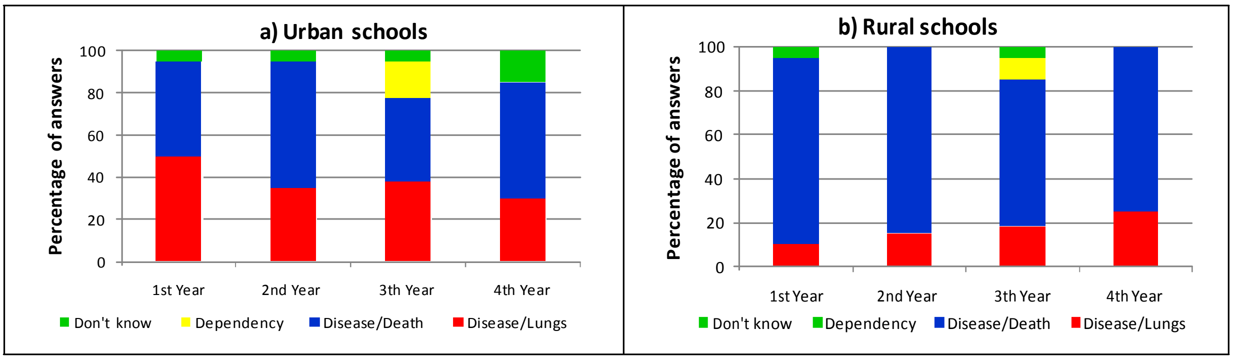

Figure 3: Categories frequencies on the tobacco effects in urban (a) and rural (b) schools.
P>0.05 between urban and rural samples, and between sub-samples of urban and rural samples.

It is interesting to note that in Urban Schools (Fig. 3a), before the formal education and more specifically in the 1st year the category "Lung Diseases" predominates with higher percentages (50%), contrary to the 2nd year that highlights the first option in the category "Diseases / Death" (60%), associating death to several diseases caused by tobacco smoke, followed by the category "Lung Diseases" with 34%. These children, in the process of informal learning, are aware that tobacco smoke has adverse effects in some organs of the human body. For them, this substance is very harmful to health and particularly to the lungs because they are darkened, the smokers have more difficulty breathing, and also because it causes various types of diseases in certain organs, including lungs, including some lung cancer. Analysing the results from the two areas (Urban and Rural) we notice that in the 3rd year the children have also revealed more formal knowledge about the dangers of tobacco, to discover that a small percentage of students (16%), refer to the category "Addiction" as one of the main effects caused by tobacco smoke in humans.
In the category "Disease/Death" children allude to death and various diseases or injured organs caused by tobacco smoking (cancer, cough, cholesterol as well as throat, stomach, breast, liver and heart illnesses). Interestingly is the fact that smoke addiction is only referred by the 3rd year pupils (1 week after teaching) from either urban or rural areas. However, as mentioned before, this was not found to be statistically significant (p>0.05).

In the iconic representation of the respiratory system there is, before the formal education, the presence of very simple concepts on the respiratory process, being almost always present the main body of this unit (lungs) or the presence of other organs that do not directly relate to breathing (Heart, stomach, intestines ...) and that, although out of context seem to be relevant for these children. By drawing schematically the child represents what he knows and what he feels through similar situations with their reality. After the formal learning, there is very significant development with regard to the anatomy and physiology of the respiratory tract, in the sense that certain simple representations gave way to more complete and scientific conceptions. In fact, in this age group, the similarity of real objects, (Lowenfeld, 1977), represent what we actually observe, learn and think (Mèridieu, 1974). Associated with this conceptual evolution in relation to the iconic representation of the anatomy of the respiratory system, there is still the presence of conceptual ideas a bit incomplete in terms of scientific.

The diagrams are produced to the lungs and from here there is no continuity of the rest of the process, relating to respiratory function. We can thus infer that the children in their answers "break" the continuity of the respiratory system, neglecting the interrelationship between the respiratory and circulatory.
So we may say that the patterns of children's previous ideas can be created (like in Fig.1) and that teaching was particularly effective in children's conceptual change regarding the respiratory tract (like in Fig. 2) but not relevant in healthy issues (Fig. 1), suggesting that teaching was not addressed to healthy, just like the pupils' textbooks. The use of these patterns of children's previous ideas about breathing and smoking may be relevant for teachers to use them in the process of pupils' conceptual change.

THE CONTRIBUTION OF SECONDARY SCHOOL SUBJECT TEACHERS TO THE EDUCATION FOR SUSTAINABLE DEVELOPMENT

Anna Uitto[1] and Seppo Saloranta[1]
[1]Department of teacher education
P.O. Box 9, University of Helsinki, Finland

Abstract: Education for Sustainable Development (ESD) integrates the principles, values and practices of sustainable development into all aspects of education and learning. The aim of this survey is to provide new information concerning to what extent subject teachers take different aspects of sustainability into account in their actions and teaching at school. Questionnaires with Likert-type scales were used to study the answers of 442 subject teachers from 49 schools in Finland. The data was reduced with a principal component analysis and an analysis of variance was used to compare teachers' answers. Depending on the subject, all teachers had specific strengths and limitations when implementing ESD at school. For instance, biology and geography teachers considered ecological sustainability significantly more often than other teachers, while language teachers were active in the education of cultural sustainability. In general, the subject was a more important factor in explaining the differences among the teachers than the teacher's gender or age. An awareness of one's strengths and limitations is important for subject teachers in order to develop their actions, teaching and co-operation in ESD at school. This study was carried out as a part of the SEED project, financed by the Academy of Finland.

Keywords: Education for sustainable development, subject teachers, lower secondary school, gender, age, large-scale survey.

INTRODUCTION

The aim of Education for Sustainable Development (ESD) is to integrate the principles, values and practices of sustainable development into all aspects of education. During the last decade, ESD has been increasingly taken into account in formal education around the globe (UNESCO, 2009). The consideration of all aspects of sustainability is important in ESD, though aspects involving ecological dimension have traditionally been emphasized (Rajakorpi & Rajakorpi, 2001; Pepper & Wildy, 2008; Breiting & Wickenberg, 2010). In Finland, according to the National Core Curriculum for Basic Education (NFBE, 2004), natural diversity and preservation of environmental viability is included in the underlying values of basic education. The curriculum also includes "Responsibility for the environment, well-being and a sustainable future" as a cross-curricular theme and, according to the NFBE (2004, p. 39), schools should teach "future-oriented thinking and the building of the future upon ecologically, economically, socially and culturally sustainable premises". In the learning objectives and core contents of different school subjects, goals linked to ESD are also mentioned. Thus, subject teachers have an important role in teaching sustainability issues.

In Finland secondary school subject teachers are specialized in two or three academic disciplines. The qualification required for subject teachers is the master's degree at a university. For their master's degree, subject teachers need to have completed basic, intermediate and advanced studies in their major subject, and basic and intermediate studies in their minor subjects, one of which is pedagogical studies at a department of teacher education in a faculty of behavioural sciences. These studies take about five years, but do not include special courses on ESD. However, sustainable development is a complex and controversial subject, and for the discipline-based teachers ESD may be a challenge.

According to UNESCO (2009), one important aspect in ESD-related research is to identify and analyze ESD's evolving contribution to the educational community. For instance in Finland, ninth grade students' pro-environmental and pro-social values and attitudes as well as their interest in environmental and human issues have been found to be interconnected (Uitto and Saloranta, 2010). Uitto, Juuti, Lavonen, Byman and Meisalo (2011) also found that ninth grade students' interest, values and attitudes to science-related environmental issues correlated with each other. To develop ESD at school, it is important to know how the teaching on sustainability issues by different subject teachers meets the world of today's lower secondary school students. This study was carried out in a subproject of a Finnish SEED research project *Sustainable Food Education for Self-Efficacy Development – SEED – How to encourage future citizens to act for a sustainable society,* 2009-2011. Specific questionnaires to survey the factors behind primary and secondary teachers', students' and headmasters' sustainable actions at school were developed. The aim of the present study is to figure out to what extent subject teachers take different aspects of sustainability into account in their 'whole-school-approach' actions and teaching at school. In this study, teachers' activities in all fields of sustainability were investigated. The questions for our research are:

- How often subject teachers implement different aspects of sustainability in their actions at school and in their own teaching?

- Do subject teachers differ from each other in teaching ecological, economic, social and cultural sustainability?

- What is the relative importance of gender, age and the teacher's subject in explaining the results?

MATERIAL AND METHODS

The data was collected in February 2010 in Finland. The questionnaire contained sections to elicit responses from teachers on items concerning actions and teaching on ecological, economic, social and cultural sustainability at school. For instance, the teachers were asked how often they used to carry out 'whole-school approach' actions, such as saving energy or materials at school, or considered different aspects of sustainability in their teaching. The commonness of different activities was rated on a five-point Likert-type scale: 5 = very often, 4 = rather often, 3 = sometimes, 2 = rather seldom, 1 = very seldom.

Fourteen questionnaires were sent to each of the randomly selected 54 lower secondary schools, of which five were Swedish - speaking schools. Altogether 49 schools returned questionnaires from 442 subject teachers (316 women and 122 men). The response rate for the selected schools was 92%, and for the teachers' questionnaires, 60%. The teachers were grouped to four different age groups: 21-30 years (13%), 31-40 years (25%), 41-50 years (31%) and >51 years (30%). The teachers were also grouped according to their major subject. The grouping was made using a combination of two subjects, if the teaching subjects were closely connected as major and minor subject and usually taught by the same teacher, such as mother tongue and literature, history and social studies, physical and health education, or religion and ethics. Finnish as the mother tongue and Swedish as a second national language were the most common subjects of the language teachers. The third common language was English. Because there were not many language teachers that had Finnish as second national language or French, German, Russian and other language as their major subject, they were combined to form a group of “other language teachers” in this study. Altogether 16 teacher categories were formed. A principal component analysis (PCA) was used to identify the latent variables. Summed scales were calculated by summing up original items according to the model of the PCA. The summed scales were then rescaled from 1 (lowest) to 5 (highest) (Table 1).

RESULTS

In the summed scales, the number of items varied between two and ten and the internal consistency (Cronbach’s alfa) from 0.4 to 0.9. Social sustainable actions, meaning co-operation and actions for the welfare of students and others teachers, were the most common contribution of subject teachers to ESD at school (Table 1).

Table 1. Means and standard deviations of the summed scales. *M* = mean, *SD* = standard deviation.1=lowest score, 5=highest score.

PCA	*Latent variables*	*N of items*	*Index of commonness*	
1	*One’s own sustainable actions at school:*		*M*	*SD*
	- Ecological sustainable actions	4	2.7	0.8
	- Co-operation in and outside the school	4	3.0	0.8
	- Social sustainable actions	5	4.2	0.4
	- Saving materials & energy in own work	2	4.0	0.8
2	*Ecological and economic sustainability in one’s own teaching:*			
	- Environmental issues	9	2.5	0.9
	- Sustainable food chains	3	2.4	1.0
	- Consumption habits	4	2.8	0.9
	- Recycling & waste sorting	3	4.1	1.0
3	*Social and cultural sustainability in own teaching:*			
	- Cultural heritage & multicultural issues	8	2.8	1.0
	- Tolerance & human wellbeing	6	3.5	0.8
	- Democracy at school & local level	4	2.7	0.9
	- Food in different cultures	3	2.7	1.1
4	*Consideration of values and responsibility in one’s own teaching*:			
	- Environmental values & responsibility	10	2.6	0.8
	- Challenges in economic sustainability	5	2.4	0.9
	- Human values & responsibility	4	3.4	0.9
5	*Self-efficacy in teaching*:			
	- Ecological sustainability	5	2.9	0.7
	- Social sustainability	6	3.3	0.5
	- General teaching, interaction with students	4	3.7	0.5
	- Influencing decision making at school	3	3.6	0.7

Ecological sustainable actions, such as saving materials and energy, were also common among teachers. More demanding sustainability actions, such as attempts actively to develop ESD at school were carried out less frequently.

In teaching, in terms of ecological sustainability the most often considered themes were recycling and waste sorting, while more specific themes, such as environmental issues and consumption habits were considered frequently. In social sustainability, tolerance and human wellbeing were quite commonly considered themes. For values and responsibility, human aspects were more commonly considered than ecological or economic aspects. Teachers' self-efficacy was higher in general teaching and interaction with the students or in influencing decision making at school than teaching ecological or social sustainability.

Examples of teachers' activity in considering different themes of sustainability are presented in Figures 1-2. For instance, biology and geography teachers contributed more often to education on environmental issues than all the other teachers (Figure 1). Recycling and waste sorting were also considered most often by biology and geography teachers, but also in home economics, visual arts and crafts. Sustainable food chains were considered most by the teachers of home economics, but consumption habits occasionally also by other teachers.

Tolerance and human wellbeing was rather commonly considered by all teachers, especially by teachers of home economics, physical education, biology, geography, religion and music (Figure 2). Democracy at school and at local level was considered mostly by the same teachers as those just mentioned above, but it was a more demanding issue. Cultural heritage and multicultural issues was considered most by the teachers of mother-tongue, history and social sciences, religion and ethics, music and visual art. Food in different cultures was considered most by the home economic teachers.

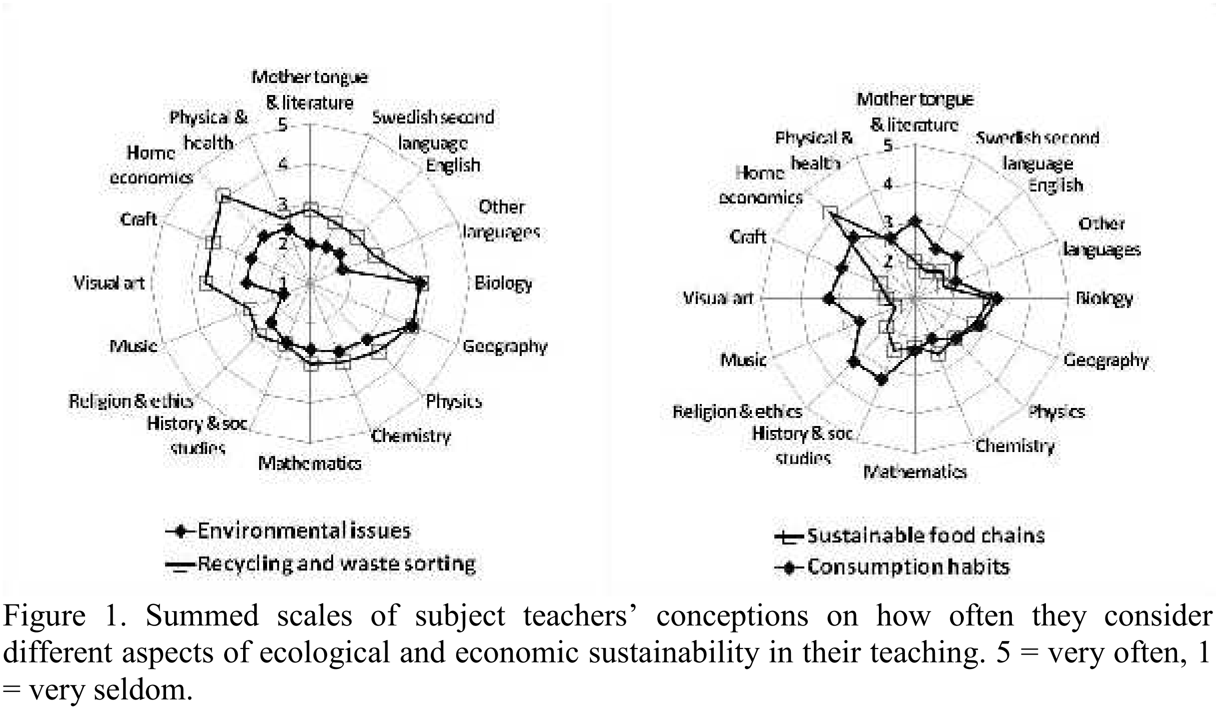

Figure 1. Summed scales of subject teachers' conceptions on how often they consider different aspects of ecological and economic sustainability in their teaching. 5 = very often, 1 = very seldom.

To figure out the relative importance of the independent variables, multivariate analysis of variance was conducted with the sex or age group and the subject of the teacher as independent variables. Teaching on environmental issues, consumption habits, recycling and waste sorting, cultural heritage and multicultural issues, tolerance and human wellbeing, and democracy at school and local level were the dependent variables.

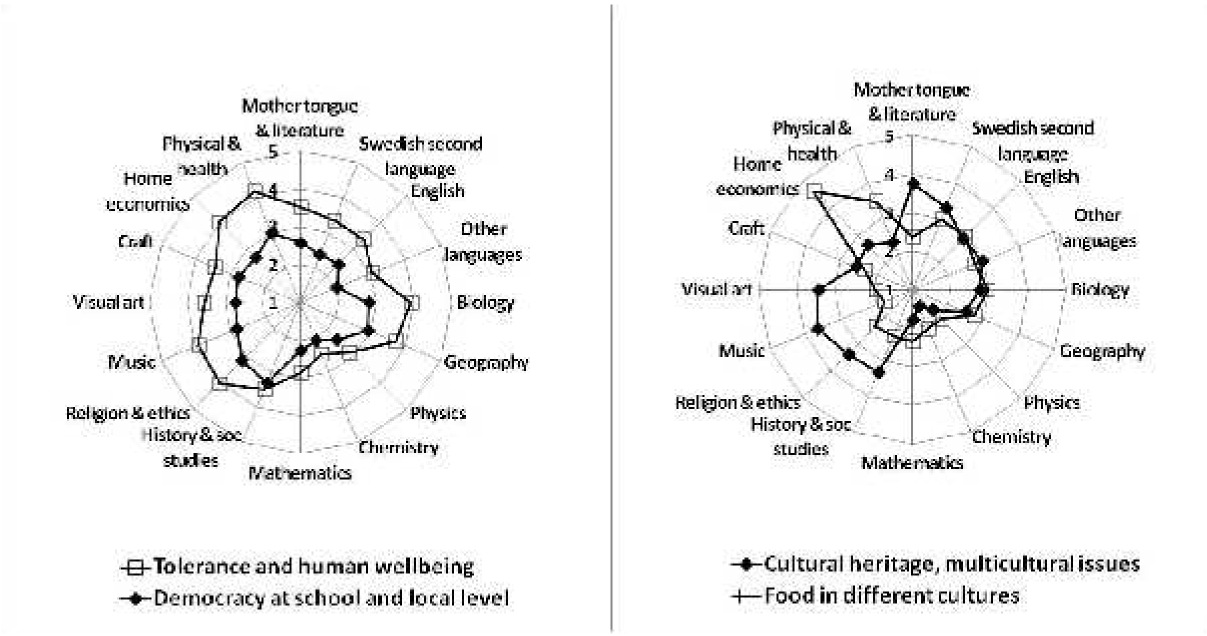

Figure 2. Summed scales of subject teachers' conceptions on how often they consider different aspects of social and cultural sustainability in their teaching. 5 = very often, 1 = very seldom.

When studied in association with gender, the effect of a teacher's subject was significant and large ─ Wilk's Lambda = .16, $F(90,2194) = 9.31$, $p < .001$, $\eta^2_p = .26$. The effect of gender was also significant ─ Wilk's Lambda = .95, $F(6,389) = 3.71$, $p = .001$, $\eta^2_p = .05$. There was also a significant interaction between gender and the teacher's subject ─ Wilk's Lambda = .74, $F(90,2194) = 1.33$, $p = .02$, $\eta^2_p = .05$. Follow-up pairwise comparisons showed that for instance democracy at school and at local level was more commonly taught by male than female teachers. When was the association between age and teacher's subject compared, the effect of the teacher's subject was again significant and large ─ Wilk's Lambda = .88, $F(18,1019) = 2.4$, $p < .01$, $\eta^2_p = .29$. The effect of age was also significant ─ Wilk's Lambda = .13, $F(90,2031) = 3.71$, $p = .001$, $\eta^2_p = .04$. In general, the oldest age group (> 51 years) used to consider sustainability issues more often than the youngest age group (21-30 years).

CONCLUSIONS AND IMPLICATIONS

During the past few decades ESD has been understood mostly as education concerning ecological aspects in Sweden and Denmark (Breiting & Wickenberg, 2010) and in Finland (Rajakorpi & Rajakorpi, 2001), although it should be more holistic including economic, social and cultural sustainability. Although a "whole school approach" is important, subject teachers have a specific opportunity to integrate different aspects of sustainability into their everyday teaching.

This study revealed that all subject teachers took aspects of social sustainability, such as tolerance and wellbeing rather often into account, in their everyday actions and in their teaching. However, depending on the subject, all the teachers had specific strengths and limitations, in terms of considering ESD. For instance, ecological sustainability, environmental values and responsibility were important for biology and geography teachers, but very rarely considered by language and music teachers. Teachers of physics, chemistry and mathematics occasionally considered fact-based ecological sustainability, but their contribution in economic, social and cultural sustainability was low. Language teachers were most active in cultural sustainability, but they rarely considered economic and ecological viewpoints in their teaching. In her study, Borg (2011) found similar results when studying how teachers from different disciplines understand and implement education for sustainable development in their teaching in Sweden. Her results showed that there were many subject-bound barriers to the successful implementation of ESD.

Awareness of the strengths and limitations of one's own teaching and awareness of other teachers' ways of considering sustainability issues would be important for subject teachers, when developing their 'whole-school approach' actions, teaching and co-operation in ESD at school. ESD should be taken into account in teacher education and when organizing further training for in-service subject teachers so that their discipline-based special know-how and needs for development are also taken into account.

The analysis of the SEED data will be continued in the future, by for instance studying the interaction between teachers and students in ESD.

GLOBAL WARMING: A CASE STUDY OF EIGHT FRENCH TEACHERS' INVOLVEMENT IN EDUCATION FOR SUSTAINABLE DEVELOPMENT

Benoît Urgelli[1] and Laurence Simonneaux[2]

Abstract: Inclusion of global climate change (GCC) in education for sustainable development (ESD) challenges this socioscientific issue being particularly complex with contradictory scientific data as well as ethical and social considerations.

In order to analyse how teachers deal with this issue, we asked two groups of four high school teachers of different disciplines how they integrate this topic when teaching 16-18 year old students. We proposed to develop teaching resources for ESD, using mediated productions concerning GCC issues.

Our analysis of their proposals and interviews showed that teachers prefer to develop individual disciplinary resources, preserving the integrity of their teaching discipline, hence giving a representation of non-socialized science. Their own ecological beliefs and their epistemological approach, mobilizing allies' media supports, were focused on different controversial and educational aims, corresponding to *positivist*, *interventionist* or *critical education*. Between neutrality, balance and commitment, four teaching attitudes appear, depending on the personal interpretation of the teacher's role in ESD. Nevertheless, collectively, with a multidisciplinary approach which is not adapted to the complexity of the topic and despite a declared neutral and impartial approach, the educational aim is more critical, for instance including discussions about political choices of nuclear energy or biofuels to alleviate the GCC.

Because facing a socioscientific issue leads to different controversial educational aims, this case study militates for a national debate around professional and educational ethics promoting a democratic commitment of students.

Keywords: climate change, sustainable development, teachers' attitudes, education, ethic.

THEORETICAL BACKGROUND AND RATIONALE

As Sadler and al. (2006) noticed, *part of the complexity inherent to socioscientific issues stems from their inevitable associations with ethical considerations* […]. *Ethical concerns are among the most important factors for individual socioscientific decision-making*. Fixing attention on mediated and controversial discourses regarding the human responsibility on global climate change (GCC) shows that ethical and epistemological conflicts are expressed. That's why we consider connections between climatic risks assessments and the political project of sustainable development as a socioscientific issue. Because global warming is not a free-value issue, in an educational project for citizenship facing this topic, values should not be excluded: *values help establish how science is conducted and help determine how results are interpreted and used* (Sadler and al., 2006).

In France, ten years after the Rio summit (1992), the promotion of education for sustainable development (ESD) defined national standards (Ministère de l'éducation nationale, 2004 and 2007), perhaps with *the intention of persuading people* […] to *promote the policies that will help to alleviate* socioscientific problems (Gayford, 2002) like GCC. But several stakeholders declared that the educational aim could not be teaching persuasive choices but rather an education for responsible choices, enabling the democratic empowerment of students. To solve this ambiguity, they suggested teachers maintain an attitude of neutrality in order to avoid students' indoctrination (Cotton, 2006). This neutral position was criticised by Kelly (1986) and Oulton (2004). According to them, if teachers make their own position explicit facing a socioscientific issue and encourage students to criticize them alongside other positions, then youthful citizens will be aware of potentials bias and encouraged to develop an independence of thought, understanding the complexity of the issue studied.

We consider that ESD must be a critical education *for democratic and transformative action* (Giroux, 1987) in which teachers could adopt *commitment impartiality* around democratic values, rather than the *myth and misguidance of a value-free and non disclosing neutrality*. The educational aim is to *catalyze the critical intelligence and civic courage of both youthful citizens and ourselves* (Kelly, 1986).

PURPOSE AND RESEARCH QUESTION

Our research aims to analyze and discuss this controversy regarding educational aims and teachers' attitudes. Through the proposition of including the GCC issue in French ESD program, our research question is how eight high school teachers deal individually and collectively with the complexity of a not-free value issue and with the expression of their own beliefs in an educative project.

Methods

Teacher Sex	*Subject taught*	*Area of exercise*	*Highest degrees*	*Levels of experience*
F	Physics - Chemistry	*High school in Grenoble*	*Bachelor*	*15 years*
F	Biology - Geology		*Master*	*5 years*
M	History - Geography		*Master*	*4 years*
F	Economics - Social sciences		*Master*	*4 years*
F	Economics - Social sciences	*High school in Lyon*	*Bachelor*	*26 years*
M	Physics - Chemistry		*Master*	*12 years*
M	Philosophy		*Bachelor*	*12 years*
M	History - Geography		*Master*	*6 years*

Table 1: high school teachers' background information

Involved in an annual work contract with the French institute for educational research (INRP), two groups of four high school teachers (teaching natural science or social science) have accepted to develop resources related to GCC issues, in order to contribute to teacher training for ESD.

For eight months, from November 2006 to June 2007, we interviewed them on *educational aims*, *mediated supports choices* and *socioscientific discourses* on their teaching proposals published on a public website for teacher training.

Each teacher produced an average of nine proposals and was interviewed twice, for individual semi-structured interviews lasting about 90 minutes. For each group of four teachers working in the same high school, two workshops of two hours were organized in June 2007, an occasion to highlight the *dominant doxa* regarding ESD. All these exchanges were audio-recorded and transcribed to analyse the teaching model supporting proposals and the teacher's pedagogical involvement on ESD.

RESULTS

According to the discipline they taught, teachers have produced disciplinary resources exploring concepts like the physics of the greenhouse effect, the global carbon cycle, the geography of climate risks, the demography, sustainable development and economy, or the philosophical analysis of the relationship between nature and technology.

But independently of the subject taught, different aims for ESD appear for each teacher. Adopting a neutral and balanced attitude (the mythic *neutral impartiality* according to Kelly, 1986), in order to avoid using their position of authority to promote their own opinions, teachers all declared they wanted to help students develop civic capacities critics.

For half of the teachers, convinced by man-made climate change, this socioscientific issue must contribute to make students aware of the environment, like a pretext-object used to achieve an *interventionist educational aim*. They used partial mediated supports like the documentary film *an inconvenient truth* (Guggenheim, 2006) where controversies are excluded. Medias are used like allies, especially when mediated beliefs about GCC are shared with the teacher. In this case, the teacher followed an *exclusive partiality* attitude (Kelly, 1986).

Some other teachers achieved *a positivist educational aim* when they considered that they were not able to deal with complexity and ethical considerations of the socioscientific issue. Because they exposed students exclusively to official and consensual disciplinary content, their attitude was an exclusive *neutrality* (Kelly, 1986).

In the same high school in Lyon, geography and philosophy teachers proposed a *critical educational model* where controversies of the question were not avoided. In an individual but multidisciplinary approach facing epistemological and ethical considerations, different mediated viewpoints were exposed. Both teachers adopted an attitude that could be qualified as *impartial commitment* (Kelly, 1986). But with an educational approach far from interventionist national ESD standards adopted by his colleagues, the geography teacher felt then a risk of marginalization.

During collective workshops, the individual tendency to maintain the integrity and the legitimacy of his/her own discipline lead to a pluridisciplinary fragmentation of socioscientific complexity. But in this context, all teachers adopted a common critical educational aim. They collectively decided to deal with topics related to political solutions presented like alleviations against GCC (nuclear energy in the high school of Lyon, and biofuels in Grenoble). Excepting the philosophy teacher who was convinced by the necessity of adopting an attitude of impartial commitment facing socioscientific controversies, they all supposed that they had to expose disciplinary and free-value knowledge, adopting a neutral attitude in debates, in order to leave students developing critical viewpoints by themselves about complexity and the values of the GCC issue.

CONCLUSIONS AND IMPLICATIONS

It seems that many parameters must be taken into account to analyse declarations and teaching proposals of the eight teachers. In the teaching context, they dealt with the balance between their *ecological beliefs* of human responsibilities on socio-environmental crisis and their *epistemological viewpoints* of the scientific assessments. Their visions of the *teacher's attitude* facing a controversial and not free-value topic must also be taken in account. All these parameters lead to three kinds of educational aims, where different attitudes are related to the *supposed influences* that the teacher could have on students' viewpoints.

Even if the disciplinary fragmentation of complexity could be an impediment for integration of a socioscientific topic, we noticed that collectively a shared critical educational aim is expressed which erased the interventionist model. Through debates between teachers, the collective situation could indicate possible progress toward a democratic citizenship education.

For a teaching inclusion of complex data and ethical considerations, we have seen that *impartial commitment* attitude was not unanimously adopted and so probably controversial. If we refuse to debate collectively with ethical considerations that are among the most important factors for individual decision-making, especially around the perspective of a common future of humanity, we risk rendering the democratic project of a civic ESD insignificant. Because excluding complex and ethical dimensions from teaching lead to a depoliticization and a disempowerment of teachers' activities, and so impede the student's training for active participation in a society largely influenced by science and technology, a breakdown of the traditionally supposed free-value teaching is necessary. Today there is a need for debates on the professional ethic for teaching a socioscientific issue, in order to restore the global meaning of citizenship in science education and to unlock a potential for pedagogical innovation.

SCHOOL SCIENCE AND PUBLIC AWARENESS: A GEOLOGICAL WALK THROUGH TIME (FOZ DO DOURO - PORTO, PORTUGAL)

[3]Oporto Townhall, Oporto, Portugal

Abstract: Citizens need to be scientifically literate in order to be able to contribute to decision making about issues that have scientific dimension. In order to help school science to promote citizenship, a field trip was organized according to Orion's model (1993), in a beach area called Foz do Douro in Porto, Portugal. The field trip had six study stations and educational materials, (including posters, field guides, banners and a film) were specially elaborated to help students and lay visitors to follow the cover story – a geological walk through time. Many school contents were taught during the field trip, helping the curricular development, but it also had the intention of public awareness of geological aspects like, for example, geological heritage. Literature revision reminds us that it is necessary to promote such field activities so that geology is learned through practice and not only from books. Although attempts to link school science and citizenship tend not to be successful in the long term, it was expected that field trips, science school and public awareness of science, together could promote the achieving of a scientifically literate citizenship.

Keywords: school science, public awareness of science, field trip, citizenship, Orion's field trip model.

FIELD TRIPS, SCHOOL SCIENCE AND PUBLIC AWARENESS OF SCIENCE

The 21st century strengthened Science Education goal to involve students in lifelong education and to participate in the on going debates about the changes occurring in society, reinforcing the need to develop citizenship competencies. This goal raises (again) the question of what kind of education in science would prepare students for their role as citizens in a rapidly changing world? Although the answer to this question may consider a number of justifications, we have to recognize the value of enhancing the public awareness of science as a social responsibility that can, and should, help the school science education to involve scholars in 'citizen science' (Jenkins, 1999). The fact is that, besides helping lay citizens understand a number of important scientific concepts, public understanding of science has implications for the form and content of school science education. This concern of school science classes to prepare students to play a constructive role as citizens in the society is perhaps the major focus of international projects, like TIMSS (Trends in International Mathematics and Science Study) and PISA (Programme for International Student Assessment), which emphasise the importance of developing the scientific literacy of students. Hence it is natural to require a relationship between school science and the general public's awareness of science, fact that led to the recognition of science learning as taking place in a continuum of formal and informal venues (Gilbert, 2010).

Due to the fact that little was made for the general public, learning science in informal environments is growing rapidly in extension and diversity. Informal education has acquired increasing importance as an element of promoting activities which enhance the public understanding of science and also as a complement to formal learning. Although we know that the public's awareness of science had developed not due to school experiences but to popularizers of science (Fensham, 1999), we all recognize the relevance of interactive museums and public science centres as important educational resources.

A field trip is another educational means that has an important role to play in developing student's scientific literacy and enhancing both cognitive and affective dimensions. According to Fuller et al. (2003), students perceive fieldwork to be beneficial to their learning, because through it they develop subject knowledge, acquire technical and transferable competencies, and interact socially with their teachers and peers. The same authors also claim that the value of field trips lies particularly in providing students with a better sense of the real world and direct experience with concrete phenomena. It can be developed as both a formal curriculum activity and as an informal awareness of science experience (Lima et al., 2010). These informal activities are not always conducted in a manner that maximise learning. However, considering the importance of field trips regarding school science and public awareness, a geological walk through time in Foz do Douro (a beach area in Porto, Portugal) was organized.

Considering the need to find a theoretically supported alternative to the kinds of field trips generally put into practice, the research team decided to organize this activity based on the model proposed by Orion (1993) (although some necessary adaptations were made, so as to promote the field trip as both formal and informal). Many geological contents were taught during the field trip (geological dimensions of time and space; different types of rocks, rock erosion …), ensuring the curriculum development and also aiming to promote public awareness, namely preserving geological heritage. It is necessary to develop such field trips so that geology is learned through practical work in an outdoor environment, rather than just from a theoretical perspective (Van Loon, 2008).

The field trip: A Geological walk through time (Foz do Douro - Porto, Portugal)

Some members of the Centre of Geology of the Faculty of Science of Porto University with members from the Porto Townhall organized a field trip in Foz do Douro, both as a learning resource, for middle and high school's students, and as a public understanding of science activity.

According to Orion's model (1993), in formal field trip activity, the stage of preparation for a field trip takes place in the classroom or laboratory and can be of variable duration. Orion e Hofstein (1994) point out the importance, in this unit, of reducing the "novelty space" (psychological factors, geographical factors and cognitive factors) to the minimum, related to how familiar the visitor is with the place to be visited. However, in this field trip, used as a formal learning resource and as an informal public awareness activity, this preparation unit did not occur in the classroom. The pre-visit unit was given by a monitor as soon as the students and lay visitors arrived at the location. The monitor resorted to a trip guide and a film illustrating the geological history of the area that were specifically produced for this field trip. In each one of the six study stations in the second unit of the field trip, considered the core unit of the module, trip guides, posters (figure 1), instruments of orientation, and other educational materials were used. It was expected that a post-trip unit would take place in the classroom (formal activity) or in the small centre which had been created to welcome the visitors (informal activity).

Figure 1. Poster in Foz do Douro

Figure 2. Students during a field trip

The cover story of the field trip involved a geological walk through time in an area extending over a series of small beaches between the Douro river mouth and the S. Francisco Xavier fort. The geological story of this metamorphic complex began many million years ago at a time when planet Earth was very different from that which we know today. In fact, both the film elaborated to reduce novelty space and the study stations selected invited the visitors to go back in time, to about 1000 million years ago, when supercontinent Rodinia was being formed.

Continuing the field trip, visitors travel through the break up of Rodinia, about 750 million years ago and the regrouping of its fragments to form Gondwana, about 650 to 550 million years ago. The field trip finishes in outcrops formed during Carboniferous and Permian periods (359- 251 M.y.). With the closure of the Rheic Ocean in this period, the Laurasia and Gondwana continents collided to subsequently form the Pangea supercontinent.

The origin of the variety of rocks observed during the visit can be explained by the story of these geological events. This area has also been classified (since 2001) as municipal natural heritage because it constitutes one of the rare outcrops of the city that demonstrates unique characteristics such as variety of lithologies, geological structures and geomorphologic features (figures 3 and 4). In fact, these outcroups constitute a natural laboratory where an understanding of geological phenomena and events become more accessible.

All of these aspects make this area a privileged place for those school teachers involved in teaching Natural Sciences or Geology.

Figure 3. Giant pot

Figure 4: Folds

On the other hand, it is also a Geological Heritage of undeniable scientific and educational value that can be used in a field trip with both cognitive and social gains, demonstrating that school science and public awareness of science together can promote the achievement of a scientifically literate citizenry.

CONCLUSIONS AND IMPLICATIONS

As citizens must be scientifically literate in order to contribute to decision-making about issues that have a scientific dimension, school science uses informal activities as educational resources. The geological "walk through time" developed in Foz do Rio Douro is an example of how a field trip can be developed as a continuous formal/informal activity of teaching, learning and science awareness.

In 2008 the Interpretative Centre (where some complementary activities in the field trip can take place) opened to school visits and to general public, having received an interesting media coverage. Because Foz do Douro is often visited by many tourists, the field guides and posters were written in Portuguese and English and pamphlets were also divulged in French and Italian.

Finally, this project was funded by the Foundation for Science and Technology (FCT-Portugal) and regarding the quality of the educational materials and the importance of the geological awareness, Porto Townhall won an honour mention in 2005 and the Geoheritage prize in 2009, both given by the group ProGeo-Portugal (The European Association for the Conservation of the Geological Heritage).

REEXAMINATION OF HOW A SCIENCE MUSEUM SHOULD BE AND ITS REGENERATION AS A COMMUNITY-BASED MUSEUM

Atsuko Yamanaka[1] *and Shogo Kawakami*[1]
[1]Gamagori Museum of Earth, Life and the Sea

Abstract: the Gamagori Museum of Earth, Life and the Sea had been an exhibition-centered museum. Those who visited the museum once, rarely revisited. Thus, the number of visitors during 2009 dropped to 19,256. In an attempt to reverse this trend, various plans have been implemented since 2010 such as science workshops and school visit programs. As a result, the number of visitors increased to 34,435, 1.79 times higher than the previous year. The number of visitors for paid exhibitions reached 23,031 in 2010 compared with 18,395 in 2009, an increase of 1.25 times. The workshop participants also visited the exhibition room, which means the workshops and other experience-oriented programs attracted new visitors. Moreover, 55 schools and institutions, 3,764 students and teachers participated in the school visit program, which fostered closer cooperation with schools. Through these programs, a local human resource network has been formed, establishing a system whereby the local community supports its science museum.

Keywords: reform of a science museum, cooperation with schools and local communities, establishment of human resource network, workshop

PURPOSE

It is widely pointed out that science museums should strengthen cooperation with society. In relation to the issue of how museums should cooperate with local schools, Griffin (1998) investigated a framework to facilitate students' learning in museums. Kawakami et al. (2003) proposed ways to use science museums in school education. Braund and Reiss (2006) proposed that laboratory-based school science teaching needs to be complemented by out-of-school science learning that draws on the actual world (e.g. through fieldtrips), the presented world (e.g. in science centres, botanic gardens, zoos and science museums), and the virtual worlds that are increasingly available through information technologies. The Minister of Education, Culture, Sports, Science and Technology of Japan (2008) recommended that schools use science museums and similar facilities as educational tools. Marcotte (2007) proposed a Web-based technology to support learning through museums. Yamanaka and Kawakami (2008) conducted science lessons for senior high school students at museums, and these lessons were highly regarded by the students who attended.

The Gamagori Museum of Earth, Life and the Sea is a science museum located in a small city with a population of about 80,000 in Japan. Due to financial difficulties and a decrease in number of visitors, discussions were held on how the museum should be reformed, keeping in mind the possibility of closure in 2007. After one year of intensive discussions, it was decided to continue the museum for the Gamagori citizens, based on its close relation to the local community and focusing on the collaboration with the local community and schools.

The objectives of the reform strategies are as follows:

- To promote frequent visits to the museum by elementary school students and their parents, through incorporating hands-on experience into the museum's programs.
- To strengthen collaboration with schools by providing science classes at schools and enhance the museum's identity as "a science education facility in cooperation with school education".
- To establish a "human resource network" organically connecting people who want to learn and people who want to teach or disseminate information, in cooperation with members of the local community, including residents, companies, universities, schools/other educational institutions, and tourism facilities so that the museum can function as a hub for science education. On top of that, this network will encourage more frequent utilization of the museum by local people by functioning as a regional "lifelong learning and community activity center".

With the aim of contributing to the revitalization of museums and science museums, this report introduces the successful case of the Gamagori Museum of Earth, Life and the Sea, which was once in a moribund state, but which has revived and experienced a dramatic increase in the number of visitors, by implementing various reform measures.

METHODS AND STUDY PERIOD

Subject:

Gamagori Museum of Earth, Life and the Sea, in Gamagori City, Japan

Period:

This report covers the results of reform measures implemented from April 2010 through March 2011.

Questionnaire surveys

Three types of questionnaire surveys were carried out in order to clarify the current state of the museum:

- A survey on how the museum is utilized was conducted with all teachers in Gamagori City in April 2010. The questionnaires were sent to 418 teachers and 208 of them answered with the response rate 49.8%.

- Surveys were occasionally conducted with workshop participants from April 2010 to March 2011.
- Another survey was conducted in November 2010 of 28 lecturers and event organizers who took part in the workshops/science shows during August 2010.

RESULTS

Specific reform measures

- Holding science shows and workshops:
  In cooperation with teachers of the neighboring communities and local companies, the museum held science shows and workshops everyday during the May Golden Week and the August summer vacation in 2010. From September onward, such events took place every Saturday and Sunday. 48 lecturers and organizations were invited to the events, including 10 researchers, 8 teachers, (1 Education Center, 1 senior high school, 1 junior high school, 5 elementary school), 19 companies, 11 senior citizens' organization and others. The titles of the science shows were "Let's Fly Solar Balloons!", "Chemical Magic Show", "Wow! How Mys-te-rious Light Is!" while those of the workshops were: "Manufacturing One-Transistor Radio", "Bio-adventure", " An Experiment of Surface-Active Agent"," What Is Fermentation Technique?" and so on.
- Holding lecture meetings:
  Three lecture meetings designed for adults were held with lecturers invited nationwide.
- Holding science seminars:
  The target audience is adult citizens with lecturers selected from among Gamagori citizens. Three seminars were held at intervals of two months.
- School visit project:
  Museum staff visited schools to provide classes of science or integrated study. Not only science lessons but also teacher training and extracurricular activities were carried out according to requests from schools and teachers. A total of 55 visits were made.
- "Easy-to-understand, visitor-friendly" exhibition
  In pursuit of "easy-to-understand and visitor-friendly" exhibitions, various improvements were introduced such as an audio-guide developed by the museum's academic staff and new explanatory panels. An area was created in the museum where the scientific achievements of schools and companies in Gamagori are exhibited.
  Although these improvements were made to the exhibition room on the third floor, substantial refurbishment is scheduled during FY2011 onward because of the limited budget. Overall, there has not been a considerable change in this respect.

The results of the questionnaire survey with teachers

As shown in Table 1, 71 teachers have visited the museum only once. While 39 teachers have never been to the museum, 38 teachers visit rather occasionally.

As for what they desire for the museum, according to Table 2, in total 131 respondents would like science shows and workshops. As many as 64 respondents referred to school visit program in which science lessons are provided by the museum staff.

Table 1. Frequency of visit to the museum

	Number of Respondents
Never been to the museum	39
Visited only once	71
Visit occasionally	38
Visit frequently	0

Table 2. What programs do you want to utilize in the future? (multiple answers allowed)

	Number of Respondents
Science shows	87
Workshops	44
School visit	64
Film shows	69
Digital materials	22

The results of workshop participant questionnaire

As shown in Table 3, 6 to 8 year-old age group had the largest number of workshop participants with 979 children, comprising 40% of the total, followed by 741 children in the 9 to 11 year-old age group that accounts for 30%. 70% of the total participants were elementary school pupils. These children were usually accompanied by their parents, the number of whom is not included in Table 3.

85% of the participants answered that the workshop was interesting. Including those who answered “moderately interesting”, 95% of the children enjoyed the program. (Table 4)

Table 3. Age distribution of workshop participants

Age	*Number of respondents*	*Percentage*
0 to 5 years old	204	8
6 to 8 years old	979	40
9 to 11 years old	741	30
12 to 19 years old	98	4
20 years and over	319	13
Others	99	4

Table 4. Satisfaction rating of workshop participants

	Number of Respondents	*Percentage*
Interesting	2036	85
Moderately interesting	233	10
Not interesting	20	1
Others	101	4

Event organizers’ opinions

A questionnaire was sent to 28 organizers of workshops and science shows and 21 of them responded.

The motives or objectives of their participation were as follows: contribution to society/community: 9; dissemination of science education: 5; and company public relations: 3.

Most of them answered that their original motives/objectives were fulfilled and 18 of them showed their eagerness to continue their activities. (The remaining 3 people did not answer.)

Change in number of museum visitors

Table 5 shows a comparison of the number of visitors in 2009 with those in 2010:
In 2010, 23,031 visitors entered the exhibition room. This is an increase of 4,636 visitors, 1.25 times higher than the previous year. The total number of visitors, including workshop and school visit program participants, reached 34,435, an increase of 15,179 visitors, 1.79 times up from the previous year. Here, "the number of visitors to the exhibition room" means the number of people who entered the exhibition room on the third floor, paying the admission fee. In 2009, the number of visitors who paid the fee to enter the exhibition room decreased to18,395.

Gamagori citizen visitors also showed an increase of 3,677, 1.36 times higher than and the number of Gamagori Citizenship cards issued was 960, 1.44 times higher than the previous year. (Gamagori citizens can visit the museum for free of charge if they possess this card.)

Workshop participants account for most of the "visitors for workshops, lecture meetings and science seminars". The number of people who attended the first lecture was 60, while for the second meeting the number was 40. Science seminars were very popular attracting 50 attendants for the first meeting and 20 for the second.

The most successful museum commitment is the school visit program. 55 classes were provided at schools and altogether 3,764 pupils, students and teachers attended.

Table 5. Number of museum visitors in 2010 in comparison with 2009

	2009	*2010*	*increase*	*Rate of increase*
Number of exhibition room visitors	18395	23031	4636	1.25
(Gamagori citizens)	(2710)	(3677)	(96)	1.36
(Number of Citizenship Cards issued)	(665)	(960)	(295)	1.44
Workshops/lectures/science seminars	100	7640	7540	76.4
School visit (science classes), etc.	761	3764	3003	4.95
Total	19256	34435	15179	1.79

Note: Figures in parenthesis indicate the number of visitors included in exhibition room visitors.

DISCUSSION

Increase in number of museum visitors

Griffin (1998) suggested creating a framework for utilization of science museums. The Gamagori Museum of Earth, Life and the Sea has launched new operating concepts of providing hands-on experience programs, such as workshops, and of encouraging cooperation with schools, as an addition to the previous policy of holding only exhibitions. A preliminary survey of teachers discovered that they would like the museum to incorporate various scientific experiences into the museum's programs and to conduct science lessons at schools. Thanks to the introduction of these new projects, the number of visitors to the museum has steadily increased. This trend proves that the museum's objective to promote visits by elementary school pupils and their parents through integrating hands-on experiences to the museum's activities has been fulfilled. The museum will continue to make efforts in this direction.

Workshops and other event projects

95% of the questionnaire respondents answered that the workshops were either "interesting" or "moderately interesting", showing a very high level of satisfaction. Braund and Reiss (2006) pointed out the importance of hands-on experience activities at a science museum. These survey results sustain their contention. It was found that senior high school students' intellectual interest increased after visiting the museum (Yamanaka and Kawakami, 2008). Ongoing efforts prove that the museum can offer a high level of satisfaction to elementary school pupils and younger children through implementing hands-on science experience programs such as workshops.

School visit project

Griffin (1998) and Kawakami et al. (2003) investigated the significance of utilization of science museums by schools. The Minister of Education, Culture, Sports, Science and Technology of Japan (2008) recommended that schools use science museums and similar facilities as educational tools. In the case of this Gamagori museum, the number of the cases in which schools made use of the museum's school visit program increased to 55.

This fact indicates that the museum's new policy of strengthening the partnership with local schools using the school visit project as a core has been well supported. Therefore, it can be considered that the objective of the museum reform as "a science education dissemination facility in cooperation with school education" has been attained.

Building a human resource network /role of the museum as a hub

The individuals and organizations that have collaborated with the museum since 2010 under the new system are linked and called "the human resource network". Currently 48 individuals and organizations constitute the network. Almost half of the museum's workshops and other programs were implemented, with lecturers invited from this human resource network. In other words, the local science education resources are passed back to the citizens through the museum's workshops and other programs.

In response to the questionnaire of this human resource network, almost all respondents indicated that they would like to take part in such programs again. This reaction shows that the creation of a human resource network, and its utilization as an educational resource, encouraged their involvement in the museum's activities. Functioning as a hub in science education, the museum can promote utilization of the facility by local residents and fulfill the museum's objective of being "a life-long education and community activity center".

Future challenges

Many of the workshop participants are elementary school pupils or preschoolers and the school visit program is utilized mostly by elementary schools. Therefore, the next challenge for the museum is how to motivate students of local junior high schools and senior high schools to visit the museum.

The expansion of experience-oriented programs led to an increase in the number of museum visitors, as well as exhibition room visitors. However, the refurbishment plan to make the exhibition room more "visitor-friendly" has not yet started due to a lack of funding. The implementation of the proposed plan is critical to enabling workshop visitors to enjoy the exhibition room more. A remaining challenge for the museum is how to formulate a system to foster more frequent exhibition visits from among those who visit the museum.

SEX EDUCATION IN LEBANON AND FRANCE

Assaad Yammine[1], Iman Khalil[1] and Pierre Clément[2]
[1]Faculté de Pédagogie, Université Libanaise, Beyrouth, Lebanon
2Université Lyon 1, France

Abstract: This work is a comparison between France and Lebanon. It analyzes the conceptions of Lebanese and French teachers on issues concerning human sexuality and its education. Our goal is to highlight the different conceptions of teachers in both countries and to identify the parameters to which these differences are correlated. All the multivariate analyses conducted show two very different systems of conceptions, very significantly differentiating Lebanese teachers' conceptions of French teachers ones. French teachers, unlike their Lebanese colleagues, are more conducive to early learning topics related to sexuality to students between 6 and 15 years old depending on the subject. They are more likely to accept abortion and homosexuality, to focus on safer sex as an attitude that can reduce the spread of AIDS, and to consider that the teaching of STIs is not only the issue of biology teachers. The differences between Lebanon and France are not reducible to religion: each country has its own identity rooted in its specific geographical, historical, economic and cultural context.

Keywords: Sex education, Multiculturality, religion, conceptions, teachers

1 – Context and theoretical backgrounds

Sex education (SE) presents great interest at the international level. Research in several countries confirms that the promotion of SE does not encourage young people to have early sexual intercourse (Blum & Mmari, 2006, Kirby & Lepore, 2007) but rather put in evidence a positive effect on the maturity in the sexual behavior of students (Singh *& al*, 2005) and risk taking (Coyle *& al*, 2004, 2006 ; Kirby *& al* , 1997, 2005, 2006, 2007).

In 1994, WHO pointed out that sex education (SE) has to provide students, considering their representations and basics, with information and scientific knowledge that allow them to discover and understand the different dimensions of sexuality; WHO added that SE also seeks to stimulate students' thinking based on information provided to help them develop attitudes of individual, familial and social responsibilities.

According to the recommendations of international organisms such as WHO, the educational center of research and development in Lebanon (ECRD) has attempted to introduce SE in the renovated curricula of 1998. This attempt has faced many objections from several socio-political and religious authorities in Lebanon, which resulted in its total suppression from the curriculum of the EB8 class (students aged 12-13) (Circular n°35/M/99, Presidential Decree n°2066) and partial containment of the biology curriculum for the 2nd year of secondary school (15-16 years), Literature and Humanities and the 3rd year of secondary school (16-17 years) (Ministry of Education circular n°95/M/99, decree n°10227/97, Harfouch & Clément, 2001, Yammine & *al*, 2007, Yammine 2008).

Currently, a new attempt to reintroduce SE in the Lebanese teaching context is part of a project combining the efforts of the ECRD, the UNFPA (United Nations Population Fund) and the Lebanese Ministry of Education.

French curricula have, in turn, evolved considerably during the past 50 years in human sexuality. ES is currently ruled by laws and is defined as follows:
"The sex education's primary purpose is to provide students with opportunities to learn and understand the different dimensions of the –and their- sexuality, in accordance with the consciences and the right to privacy. This education, based on humanistic values of tolerance and freedom, self and others respect, should also help students to integrate positive attitudes of individual, familial and social responsibilities." (B.O N°. 46: Circular N°. 98-234 dated November 19, 1998, Sex Education and AIDS Prevention).
The introduction of SE in France was initially, and is still today, more directed to the biomedical dimension than to the promotion of health (Bernard & Clément 2005, 2007 Berger et *al*, 2007). SE in France has not met such strong resistance as in Lebanon.
Lebanese society is multiconfessional. To manage it, the Lebanese refer to the National Pact (unformulated agreement, not written, signed in 1943) to apportion the responsibilities in the government (Al-Khoury, 1956), "which gave birth a tradition where each community was responsible for providing education to its children as it wanted and where it wanted" (Quobeisy, 1998).
Beyond this diversity, there may be some Lebanese homogeneity in comparison with other countries. This relative homogeneity is in fact emerged in comparing conceptions of the Lebanese teachers to those of teachers from other countries on topics such as evolution (Clément & Quessada, 2008, 2009), or environment education (Khalil & *al*, 2007a and b).
It is for these reasons that we made a comparison of Lebanese and French teachers' conceptions, using samples large enough to identify a possible diversity of opinion within each country, but also to compare the two countries together, in order to identify whether, beyond their differences, the Lebanese teachers share common characteristics that distinguish them from their French colleagues.

Analyzed conceptions will take into account the teachers' knowledge, values and social practices (in relation to abortion, homosexuality...) and their pedagogical projects (what should or should not be taught and at what age).

2 - Research Question.

Do the Lebanese and French teachers conceptions on sexuality and SE mainly differ in terms of the nationality of these teachers (thus according to their national socio-cultural context) or are they rather based on other parameters such as their religion, the degree of belief and the religious practice, or even more on their political opinion?

3 – Methodology

It was developed in the context of the European research project Biohead-Citizen (Biology, Health and Environmental Education for Better Citizenship; 19 countries, including Lebanon and France). Teachers respond in writing, completely anonymously and in the presence of the researcher, to a questionnaire covering six topics, including reproduction and human sexuality and teaching (24 questions) as well as their religious, social and political opinions (17 questions), and other personal information (Clément & Carvalho 2007). The responses were subject to several types of multivariate analyses (Munoz & Clément, 2007, Munoz & *al*. 2009).

In each country, samples are strictly comparable: 1/6 in service teachers of primary schools (InP), 1/6 pre-service teachers of primary schools (PreP), 1/6 in-service teachers of biology (InB) in secondary schools (for Students 11 to 18 Years old), 1/6 pre-service teachers of biology (PreB) in secondary schools, 1/6 in-service teachers of language / letters (InL) in secondary schools, 1/6 pre-service teachers of language / letters (PreL) in secondary schools.
In total, 722 teachers and future teachers were surveyed in 5 regions of Lebanon (North, South, Mount Lebanon, Bekaa and Beirut) and 732 teachers and future teachers in two regions of France (Rhone-Alpes and Languedoc-Roussillon) (Table 1).

Table 1. Submission of samples surveyed in Lebanon and France. For the group of education (InB, InL etc.), cf. the text above. For religion, AGN = Agnostics, CHR = Christians, Muslims = MUS, ELS = most: "I do not want to answer" no answers + some, + a few other religions as AGN, CHR or MUS

		Lebanon	%	France	%

	5 (-)	45	6.2	532	72.7

4 - Results and Discussion

We restrict ourselves to the most significant effects, without presenting here the effects less or not significant (age, gender, educational level, etc.).
The PCA (Figure 1) performed using the 24 questions on the SE for 1454 teachers, shows a clear difference between French and Lebanese teachers.

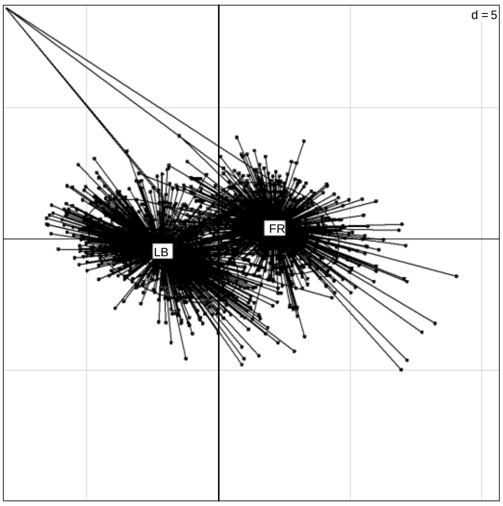

Figure 1a

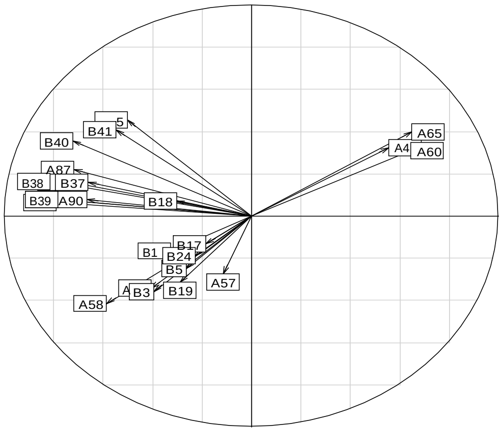

Figure 1b

Figure 1- (a) Individual points in the space for the first two discriminant axes differentiating the two countries as: FR = France, LB = Lebanon. **(b)** PCA on the SE variables (24 variables), France + Lebanon.

A between analysis, supplemented by a randomization test of Monte Carlo, shows that this difference is highly significant.

In fact, French teachers, unlike Lebanese teachers, are more conducive to early learning topics related to sexuality to students aged 6 and 15 years depending on the subject (A85 à A90 et B37 à B41). They are more likely to accept abortion (A65) and homosexuality (A41), to focus on safer sex as an attitude that can reduce the spread of AIDS (A60), and to consider that the teaching of STIs is not only the issue of biology teachers.

The analysis of the issues that most differentiate the two groups shows KVP interactions: Lebanese and French Teachers opposed or not to abortion, homosexuality, are in the same time more or less favorable to the introduction some scientific content (K) in the SE, based on their religious values (V) and their associated social practices (P).

The histogram in Figure 2a shows that while 52% of French teachers are for equal rights for homosexual and heterosexual couples, 72.3% of Lebanese teachers refuse such equality.

Homosexual couples should have the same rights as heterosexual couples.	I agree	1	2	3	4	I don't agree

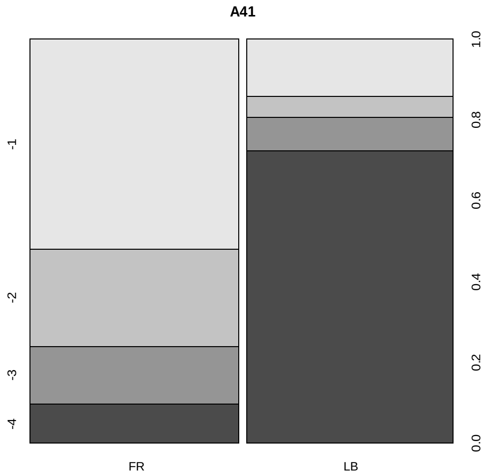

Figure 2a. Histogram of individual responses to question A41 (values 1, 2, 3, and 4 correspond to four levels of "Likert scale")

The histogram in Figure 2b shows that 71.2% of French teachers found that incest and sexual abuse are topics to be taught at an early age (the ages of 2 fields are added here), 60.8% of Lebanese teachers that are for late teaching of these topics (> 15 years) or never at school.

When do you think the following topics should be first introduced at school by teachers and/or external specialists? (Tick only ONE box per line):

Topic		Less than 6 years old	Between 6 and 11 years old	Between 12 and 15 years old	More than 15 years old	Never in school
B39.	Incest and sexual abuse	1	2	3	4	5

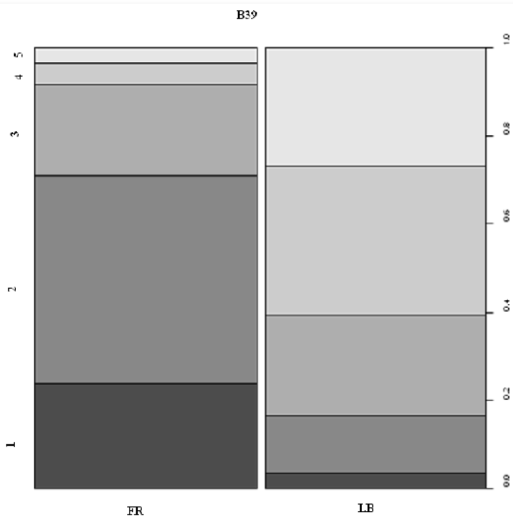

Figure 2b. Histogram of individual responses to question B39 (values 1, 2, 3, 4 and 5 correspond to five levels of "Likert scale")

The 1 454 teachers' conceptions also vary quite significantly depending on their religion, which is very different in the two countries: half of French teachers are atheists or agnostics, against 0.4% of Lebanese teachers interviewed, 65% of Lebanese teachers are Muslims (Shiites, Sunni or Druze) against 1.5% of French teachers interviewed. It is therefore not surprising that when we remove the country effect, the religion effect disappears. However, when we remove the religion effect, the country effect remains very significant, which means that Christian teachers (41.5% of the French sample, 30.1% of Lebanese teachers interviewed) have different ideas about human sexuality and its teaching (Figure 3).

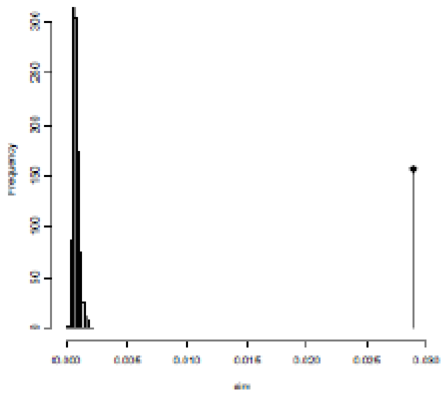

Figure 3. The test of randomization (Monte Carlo)

Finally, a co-inertia analysis between firstly a PCA on the SE variables (Figure 4a) and on the other hand a PCA on the socio-political and religious variables (Figure 4b) highlights two systems of conceptions: one characteristic of most believers and teachers practitioners, less secular (more against separation between politics and religion, hence between science and religion) are more detrimental to early education of the SE at school, less accepting of homosexuality and abortion, and they prefer stable relationships of couples to "safer sex". Most of the Lebanese teachers are in this pole. The second system of conceptions brings together teachers less religious, more secular, and more favorable to the SE in school; this pole includes the majority of the French teachers.

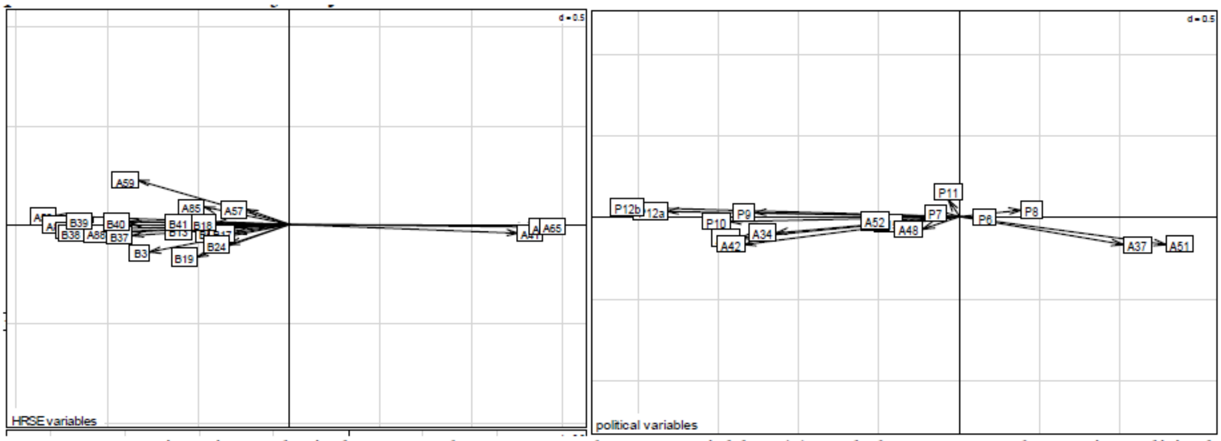

Figure 4- Co-inertia analysis between the PCA on the SE variables (a) and the PCA on the socio-political / religious variables (b).

5 – Conclusions

Beyond their religious diversity, the Lebanese teachers share ideas on human sexuality and SE, which distinguish them clearly from the French teachers. Each country has its own identity rooted in its specific geographical, historical, economic and cultural context. The relative homogeneity of the Lebanese teachers who has also emerged in comparing of their conceptions to those of teachers from other countries on topics such as evolution (Clément & Quessada 2008, 2009), or environment education (Khalil & al, 2007 a and b), explains the difficulties of implementing the SE in Lebanon. The perspectives opened by these results will be discussed in more details.

SCIENCE CURRICULUM, EDUCATIONAL POLICY

THEMATIC CLASSIFICATION OF ELIGIBLE CONTEXTS FOR A HOLISTIC PERSPECTIVE IN CURRICULUM DEVELOPMENT

Ridvan Elmas[1], *Mustafa Sahin Bulbul*[1], *Ali Eryilmaz*[1]
[1]Middle East Technical University, Turkey

Abstract: The goal of this study was categorizing the contexts according to disciplines as disciplinary, interdisciplinary or multi disciplinary. As a second goal we would like to figure out which contexts are mostly eligible for instruction and induces student interests. We designed a survey with 77 physics and chemistry contexts which were chosen systematically from high school physics and chemistry curriculums. The sample of this study was consisted of 104 pre-service student teachers from 3 different departments of the two universities in Ankara, Turkey. The determination contexts as perceived interdisciplinary and multidisciplinary can be used to design a holistic curriculum that unites many courses under the same theme. Determination of interesting contexts can be very helpful for course designers, textbook writers, teachers and educational researchers as a starting point. According to the descriptive data analyses for context discipline relationship, 77 contexts were categorized into four groups. These groups are mainly physics (44), mainly chemistry (18), both physics & chemistry (14), and other disciplines (1). The students' willingness to learn and to teach these contexts part comes out with two categories. Student teachers are equally willing to learn and teach 58 contexts and their willingness to learn was greater than to teach for 19 contexts.

Keywords: Curriculum Integration, Holistic Curriculum, Eligible Contexts, Context Based Education, Curriculum

Background, Framework, and Purpose

In the direction of the new reform trends in science education, elementary and secondary education curriculums were redesigned and disseminated by Turkish Ministry of Education. Both elementary and secondary curriculums are embraced constructivist principles, daily life activities, and multi-modes of assessment as possible as in the Turkish context (Elmas & Geban, 2010; Ozturk, Elmas & Savas, 2011). Among the others, high school physics curriculum is the one which uses context-based approach as one of its main perspectives. Context-based approach is very popular in the design framework of many reform curriculums and science projects. Salters' Chemistry, Salters' Science and Salters' Advance Chemistry 1989-1990-1992 in UK, Dutch PLON project in the Netherlands, Large Context Problem Approach in Canada, Applications-led approach in Scotland (UK), Event-centered learning in Brazil, and Chemistry in Context in Germany and the US are well known examples. The effectiveness of context-based approach in class instruction has been gathering evidence also from the literature (Bennett, Lubben, & Hogarth, 2005; Bennett, Grasel, Parchmann, & Waddington, 2007).

The success of context-based approach in school practice depends on teacher and student roles, classroom atmosphere, and students' connection with the contexts (Gilbert, Bulte, & Pilot, 2011). Students learn better when encountering contexts which support their cognitive structures in their minds. Meaningful learning occurs when contexts are enacted to the classroom instruction according to students' interests (Medrich, Calderon & Hoachlander, 2002). If the contexts presented in the instruction do not accompany with students' daily life experiences and interests, students cannot be focused to the inquiry process and lose their motivation (Conger, 2001).

Most of the researches are promoting the context-based approach but there are not many studies which fill the gap between students' interests and eligible contexts for effective classroom instruction in Turkey (Serin, 2009; Yaman, 2009; Sahin & Eryilmaz, 2010). In addition to determining the eligible contexts, using one as theme for integration of physical sciences or as a multi disciplinary way to connect many courses in the classroom instruction can be an effective way (Ioannidou & Banos, 2009). To employ one context, for integrating many disciplines in the same classes can empower students' cognitive structures in multiple perspectives about the same scientific phenomena. Focusing the real life problems without compartmentalizing the sciences into disciplines is the main principle of curriculum integration (Baykal, 2004). Beane (1995) defined the curriculum integration as;

> ''Curriculum integration is not simply an organizational device requiring cosmetic changes and realignments in lesson plans across various subject areas. Rather, it is a way of thinking about what schools are for, about the sources of the curriculum, and about the uses of knowledge.'' (p. 616)

Curriculum integration supports social meaning, technological aspects, scientific literacy, and public understanding of science (Beane, 1995). Probable four main benefits of the integrated curriculums are; holistic learning, relevancy to learners' life, development of problem solving skills, and supports Science-Technology-Society approach (Chan, 2005).

Curriculums characterized by strict disciplinary boundaries and without supporting the social and daily life aspects of students are coming to an end (Venville et al., 2002). The integration should not be artificial, arbitrary, abstract, or irrelevant to students' daily life (Aikenhead, 2003). Students do not relate their daily life issues to separated disciplines; they see the problems as a whole. What is important at this point is the how school science responds to students' needs and interests. Relevance of the contexts to what and to whom are the critical questions to clarify the issue (Mayoh & Knutton, 1997). Students, teachers, pre-service teachers and science educators are the crucial decision makers of determination of the relevant integration contexts in addition relevance to daily life and social issues are significant aspects. In this study, researchers attempted to determine the relevant contexts for integration with pre-service teachers as a first part of the study. The purpose of this study was to determine pre-service teachers' views about classification of the eligible contexts for integrated curriculum. Gender difference was also taken into consideration regarding the classification of contexts.

Rationale

Since the importance of the determining the interesting and eligible contexts, pre-service teachers are more ample to choose which contexts are more eligible for instruction for two reasons. Sometimes students' interest to an ineffective context really blocks the path to the meaningful learning of science. In addition, pre-service teachers are aware of the new educational trends and curriculum goals for more than high school students as. Classifying the contexts according to their relationships between disciplines and determining their position as a disciplinary, interdisciplinary or multidisciplinary context can be helpful for organizing a thematic curriculum from a holistic perspective. The determined multi disciplinary contexts may be seen as an inducer for a new holistic curriculum. Holistic curriculum can serve as a bridge to unite many courses and schools at the same time interval (Finch, Frantz, Mooney, & Aneke, 1997). Moreover, these appealing contexts can be easily used for teachers, textbook writers and educational researchers.

Methods

Survey, which was used in the research, was consisted of 77 physical science contexts. These 77 mix physics and chemistry contexts were chosen systematically from the high school physics curriculum, high school chemistry curriculum, and Salters' Advanced Chemistry textbooks. The goal of the survey is to capture the pre-service teachers' opinions over the discipline and context relation. The figure out the context discipline relation physics, chemistry, none and others are the options in the survey. Students were allowed to mark one or more options for each context. If a pre-service teacher marked first two options, this means that this person perceived this context is an interdisciplinary context related to physics and chemistry together. Marking physics, chemistry and others mean that this context might be a multi disciplinary one. This shows that this context has a capacity to be used as a topic in an integrated and holistic curriculum. It is also possible to use in textbooks, and activities.

In addition, the students' willingness to learn and to teach these contexts was measured according to a four level scale. The first version of survey was face validated by three science educators. After face validation, the survey was piloted with six students. The shape, organization and contexts of the survey were redesigned in a series of meetings. The sample of this study was consisted of 104 pre-service student teachers from three different departments of the two universities in Ankara. Physics, chemistry, and science pre-service teachers, who can be graduated in two years, were selected as participants for the study. The survey was applied in the classrooms by their regular instructors. There were no additional explanations made other than the written guidelines at the beginning of the survey in any class. The approximate application time of the survey was almost 15 minutes. After data cleaning and missing data analyses, descriptive and frequency analyses were done by the PASW.

Results

According to the descriptive data analyses, 77 contexts (Table 1) were categorized into four groups. In the first category, 44 contexts were perceived as related with mainly physics. However, meteors were also related with other disciplines, automobiles with both physics and chemistry. Moreover, gyroscopes context were left empty by a significant number of students. In the second category, 18 contexts were perceived as related with mainly chemistry. However, respiration and photosynthesis were also related with other disciplines. In the third category, 14 contexts were perceived as related with mainly both physics and chemistry. Ozone layer and dialyses were also related with chemistry alone. Moreover, oceans were also related with other disciplines. In the last category, DNA is the only context that is related to the others category.

The students' willingness to learn and to teach these contexts were marked as 0, 1, 2, and 3 for each item, independently. By dividing this range to four equal intervals, we get a. 0-0.75, b. 0.751-1.5, c. 1.51-2.25, and d. 2.251-3 intervals. We summarized the results into two categories. If the item means of students' willingness to learn and the item means of students' willingness to teach were the same, we put them in the first category. There are 58 contexts in this category. All contexts in this category were wanted to learn and teach in the high level (Interval c) except gyroscope context. The item mean of the gyroscope context is in Interval b. If the item means of students' willingness to learn were greater than item means of students' willingness to teach, we put them in the second category. There are 19 contexts in this category. All contexts in this category were wanted to learn in Interval d and teach in Interval c except washing machine and Saz (a Turkish folk music instrument) context. They want to learn in Interval c and teach in Interval b. In general, the students wanted to learn and teach science by using these contexts.

Table 1. "List of Given Contexts"

Light	Robbery Alarm	Automatic Door	LCD Television	Atmosphere
Detergent	Nuclear Plant	Getting X-ray	Sun batteries	Atomic bomb
Aurora	Train Rails	Frost	Processing of oil	Rechargeable Batteries
Generator	Twins Paradox	High-speed trains	Hair Dryer	Photocopying Machine
Adapters	Meteors	Human	Particle Accelerators	Detectors
Radio Waves	Mechanical weighing machine	Digital weighing machine	Elevator	Crane
Airbags	Rockets	Washing machine	Swing	Ferris wheel
Gyroscope	Boats	Tumbler	Yo-yo	Firework
Earthquake	Saz	Buffle	Speaker	Eclipses of Moon and Sun
Rear-view Mirrors	Rainbow	Fiber optic cables	Eyeglass	Radar
Dialyses	Lather	Toothpaste	Shampoos	Cars
Sunglasses	Cell Phone	Medical Drugs	DNA	Muscles
Bridges	Breathalyser (drunk meter)	Photosynthesis	The Oceans	Fuels
Artificial Sweeteners	Recycling	Fertilizer	Pesticides	Paints
Aircraft	Respiratory	Bleach	Ceramic	Soap
Stars	Ozone Layer			

According to analyses of the data regarding the gender: Table 2. displays the more prominent contexts for willing to learn column.

Table 2. "The Willingness to Learn the Concept According to Gender Difference"

Category	**Most wanted to learn**	**Less wanted to learn**
All	Particle accelerators, rainbow, rubber alarm and eyeglass lenses	Light and boat
Female	Particle accelerators, dialyses	Boat and crane
Male	Eyeclass lenses, Sun batteries	Light and soap

Conclusions and Implications

The contexts chosen from Turkish high school physics and chemistry curriculums were accepted by most of the pre-service physics, chemistry and science students. Fourteen (LCD television, nuclear plant, getting x-ray, atomic bomb, atmosphere, rechargeable batteries, human, rocket ship, firework, muscles, dialyses, recycling, oceans, and ozone layer) out of 77 contexts were perceived as interdisciplinary. Only ocean context were also perceived as multidisciplinary.

The pre-service teachers' willingness to learn and to teach most of the contexts was same but gender analyses reported some differences in preferences of some contexts. However, there are 19 contexts that they want to learn more than to teach. These are light, robbery alarm, LCD television, nuclear plant, getting x-ray, sun batteries, atomic bomb, high speed trains, rechargeable batteries, human, washing machine, earthquakes, saz, eclipse of sun and moon, rainbows, fiber optic cables, automobiles, cell phones, and recycling.

When the researchers explored the willingness to learn in terms of gender difference, there are four contexts which were wanted to learn more (Particle accelerators, dialyses, eyeglass lenses and sun batteries) and four other contexts which were wanted to learn less (Boat, crane, light and soap) than others. According to the results, researchers should be careful while choosing a context not to do a gender bias because willingness of learning contexts depends on gender. Additional studies might be designed to investigate the reasons why context preferences differ in terms of gender.

Asking students what to learn could be starting point of context-based instruction. Probably one of the best ways to minimize the number of contexts in all courses is to use the same context for different disciplines. We tried to find these contexts for physics and chemistry courses by asking questions to the pre-service teachers who are half student and half teachers.

THE CHALLENGE OF GENERIC COMPETENCES TO SCIENCE EDUCATION

Peter J Fensham
QUT/MONASH U., Australia
p.fensham@qut.edu.au

Abstract: Since 2000 there has been pressure on education systems for develop in students a number of competences that are described as generic. This pressure stems from studies of the changing nature of work in the Knowledge Society that is now so dominant. The DeSeCo project identified a number of these competences, and listed them under the headings of *communicative, analytical* and *personal*. They include *thinking, creativity, communication skills, knowing how to learn, working in teams, adapting to change, and problem solving.* These competences pose a substantial challenge to the manner in which education as a whole, and science education in particular, has hitherto been generally conceived. It is now common to find their importance acknowledged in new formulation of the curriculum. The paper reviews a number of these curriculum documents and how they have tried to relate these competences to the teaching and learning of Science, a subject with its own very specific content for learning. It will be suggested that the challenge provides an opportunity for a reconstruction of the teaching and learning of science in schools that will increase its effectiveness for more students.

INTRODUCTION

In the flurry of national reports about Science for All in the 1980s, the Science Council of Canada was alone in presciently listing *"preparation for the world of work"* as one of the four aims to be given attention if a Science for All was to be achieved (Science Council of Canada, 1984). Soon after In England, the Royal Society for the Arts (RSA) (1986) promoted the notion of education for capabilities associated with the world of work. Neither of these challenges about preparing students for the world of work in science classes were responded to by science educators in these two countries or elsewhere in other countries.

In the 1990s the OECD reported on a series of studies of young persons' transition from school to work and of the world of work itself (OECD, 1996a&b, 2000). Bayliss (1998) likewise further reviewed the world of work for the RSA . Work in developed countries, it was argued, is changing *in kind, in the requirements for performance*, and *in the permanence of one's engagement.* These changes in the world of work and employment are driven by new forms of information (ICT), which increasingly make knowledge be the primary source of economic growth. "The Knowledge Society" is an epithet that aptly describes these fundamental changes

In the Knowledge Society there is a shift in the characteristics of what it means to know. Knowledge is dynamic, like a verb, *rather than static, like a noun.* Knowledge is about acting and doing to produce new things, *rather than being the storing of bits of established knowledge.*

Value in the Knowledge Society is associated with knowing how to learn, knowing how to keep on learning, knowing how to learn with others, and seeing possibilities for solutions to problems.

Fraser and Greenhalgh (2001) listed these generic learnings with this dynamic character as *equipping students to adapt to change, to generate new knowledge* and *continue to improve performance*). DeSeCo is an acronym associated with attempts to define and select competencies as new priorities for teaching and learning (Rychen & Salganik, 2003). Three broad types of competence – communicative, analytical, and personal have resulted.

Jane Gilbert (2005) in New Zealand has provided a helpful dialogic account of both the Knowledge Society and of its demands on schooling. She recognizes the gulf between its paradigm for knowledge and learning and the paradigm of traditional schooling. In seeking a compromise she argues that competences, like *thinking, communicating, investigating,* and *problem solving*, require a context. Furthermore, students need to know that every knowledge discipline is built on such competencies as active strategies. The traditional paradigm of schooling has overemphasized the static established knowledge of the disciplines and given too little attention to their competences as disciplinary strategies. Science education in particular, has emphasized acquiring a store of established knowledge, and knowing the right answer to questions with only one correct answer

This paper discusses the manner and extent to which the capability/competence challenge has been attended with respect to Science in recent curricular reforms and discussions in Australia, New Zealand and several European countries. Two sources have been used to assess the overall curricular response to the demand for capability education: –

- detailed curriculum statements from three Australian states – Tasmania, Victoria, and Queensland, and from the Australian Curriculum and Reporting Authority
- a detailed curriculum statement from New Zealand, and
- the responses of science education experts in five European countries to a short questionnaire (available from the author) about the competences/science curriculum issues in their countries..

CURRICULAR RESPONSES TO THE KNOWLEDGE SOCIETY

Australia

Despite the lack of any coherent national debate in Australia concerning the competency paradigm, each state and national curriculum project since 2000 has specifically included some of these generic competencies as a prominent feature of the intended learning.

Case 1. Tasmania

In Tasmania, as early as 2002, a framework for a new curriculum was provided consistings of five sets of Essential Learnings, ***Thinking, Communicating, Personal Futures, Social Responsibility*** and ***World Futures.*** (Tasmania Department of Education, 2002). It is of interest to note that the words, *science, technology* and *environment*, only occur in the sub-text of ***World Futures***, and not in the first three sets that most directly make links with the generic competences.

Although this framework went on to list as one of its *Principles* that the curriculum must focus on *understanding, deep knowing, rigour and depth,* words that are familiar in the traditional paradigm of subject knowledge, the priority for these was lost among other statements that were unfamiliar to science teachers and seemed to prioritise the radically new first four sets of Essential Learnings. The rapid decision to withdraw this curriculum and revise it to a more customary approach based on six subject areas is indicative of the difficulty to provide a comprehensible and practical link between a very bold statement of intent for the demands of the Knowledge Society and what existed, and was familiar, in familiar subject knowledge-based schooling (Tasmania Department of Education, 2004)..

This revised curriculum in Tasmania stated that through all the curriculum subject areas students will learn to *reason, ask questions, make decisions and solve problems, communicate, create and convey ideas effectively and confidently, develop responsibility in the community, and understand and apply important concepts, knowledge and skills. Thinking* is 'to lie at the heart of the curriculum, and is an important goal of a balanced and quality education. Every teacher is a teacher of thinking. The skills of thinking are best taught explicitly, using the content, skills, and processes of the subject area'. However, in the revised statement for Science the word, "thinking" does not occur, a striking difference from the five other subject areas and ICT , which all specifically indicate how various thinking skills can be taught.

Case 2. Victoria
The language of Tasmania's curriculum initiative - *values, purposes, and principles* - find echoes in the Introduction to the **Victorian Essential Learning Standards, VELS,** (Victorian Curriculum and Assessment Authority,, 2007)**.** This curriculum is set out as consisting of just three connected strands of learning (schematically suggested as intertwining): **Physical, Personal and Social Learning, Discipline-based Learning** (Science is one of the six listed**),** and **Interdisciplinary Learning**

A number of Generic competences are listed under **Personal and Social Learning** while *Thinking* and *Communication* are subheadings under **Interdisciplinary Learning**.

In the **Discipline-based Learning** strand the essential knowledge, skills, and behaviours for Science are spelt out for each year level under two headings, familiar internationally for Science from at least from the early 1990s, as *Science knowledge and understanding* and *Science at work*. Under these headings none of the generic competences in the other strands are mentioned. Thus, as far as Science is concerned the intended *connectedness* of the three strands is thus almost invisible in this curriculum. Conversely, the Learning focus and Standards for **Personal and Social Learning** intend a rich variety of personal leaning, but without any direct reference to the corresponding content for learning at these levels in the **Discipline-based Learning** strand.

Case 3. Queensland
The preamble to **Learning P-12** commits this curriculum to develop three learning goals: *a solid foundation in knowledge, skills and values, an ability to create new ideas and translate them into practical application* and *generic capabilities that underpin flexible and analytical thinking, a capacity to work with others and an ability to move across subject disciplines to develop new expertise*' (Queensland Studies Authority, 2010)

Queensland uses syllabuses and guidelines to identify the content standards or required learning that is expected of students. Science is a Key learning area in Years 1-10. Assessment standards are the responsibility of teachers who are assisted by an Assessment Bank and the Queensland Comparable Assessment Tasks (QCATs) in Years 4, 6 and 9.

The introduction to Science refers to ‘the study of science helping to promote students’ personal attributes such as *perseverance, cooperation, collaboration and creativity* and *engages students in distinctive ways of thinking about and explaining events and phenomena.*

The essential learnings for science are set out under *Ways of Working* and *Knowledge and Understanding* which has a sub-heading *Science as Human Endeavour*. In the details for each year level there are explicit references to this list of generic competences, but they all come under the *Ways of Working* strand, and are not identified in, or associated with, the *Knowledge and Understanding strand.*

Case 4. Australian National Curriculum

In 2007 the new national Labor government announced the development of a national curriculum – a first for Australia with its federation of states holding the responsibility for school education. Consistent with origins in the earlier **National Declaration on Educational Goals for Young Australians** the abilities *to think flexibly, to communicate well* and *to work in teams* were to be included (ref),

In an initial document, *the Australian National Curriculum's Design*, the Australian Curriculum and Reporting Authority (ACARA) stated that schools will help students develop seven important general capabilities. These were listed as:

- *literacy,*
- *numeracy,*
- *information and communication technology (ICT) competence*
- *critical and creative thinking*
- *personal and social competence*
- *ethical behaviour*
- *intercultural understanding.,*

Brief descriptions were provided of what these capabilities meant in practice and of their importance.. The *Design* also suggests that *"some of these capabilities become more discipline-specific as the school years progress and that each capability will be represented in each learning area in ways appropriate to that area"*. In addition there was reference to what seemed to be other capabilities such as *to innovate, to solve problems* and *to engage with new disciplines (Australian Curriculum and Reporting Authority,2009).*

ACARA's Overview statement for this curriculum states that the general capabilities are to be embedded within the details of the learning areas, initially approved in 2010. The details for Science are set out in three stands, *Science as understanding, Science as Human Endeavour* and *Science as Inquiry.* The embedding has been done for each year of compulsory schooling (1-10) by associating the detailed topics in the three strands for Science in each year of schooling (1-10) in the 2010 document with one or more symbols that represent the different seven capabilities (Australian Curriculum and Reporting Authority, 2011). This association is best described as a "sprinkling on", since there is no rewriting of the learning topic to indicate how, say, *numeracy* or *personal and social capability, etc.* is to be included in the topic's teaching. Furthermore, In some years of Science not all seven symbols appear and conversely some topics that have apparent potential for including a capability are left unsprinkled.. The intention for a progression in the learning of the capabilities seems to have been subsumed as a lesser priority to the existing progression set out for the Science content. As a result the general capabilities become, at best, extra "stuff" to include in an already crowded curriculum.

New Zealand
Case 5. Given the greater degree of national debate about the Knowledge Wave in New Zealand it is not surprising to find that country's new curriculum in 2007 lists *thinking, using language, symbols, and texts, managing self, relating to others,* and *participating and contributing,* as five Key Competence intentions (New Zealand Ministry of education, 2007).

However, in the detailed statements for Science, as an identified *Learning Area*, the role of these competences, is much less clear. At most, they are subsumed under a strand entitled *Nature of science* which is intended to be "overarching and unifying". The wording of this strand reads like a classical statement of the epistemological characteristics of Science. *'Science leads to understanding about the world, it involves particular skills and methods, is durable, and is re-evaluated in the light of new evidence. Science is a socially useful knowledge system, has its own means of communication, and scientific knowledge can be the basis for societal decision making.'*

This strand in the Science statements is to be used to 'overarch and unify' the content knowledge learnt in the four traditional science disciplinary areas, but how this overarching and unifying is to be achieved is not indicated. There is no reference in the Science statements to any of the five competences heralded as the Key Competencies for this new curriculum..

Case 6 Switzerland
Eight science skills that are familiar within science are listed. When combined with specific science knowledge content they become scientific competences (relatable to the generic competences) for inclusion in the teaching of science.

to show interest and be curious	*to ask questions and investigate*
to exploit information services	*to organize, structure and model*
to assess and judge	*to develop and realize*
to communicate and exchange views	*to work self reliantly and reflect*

Case 7 England and Wales
There is general reference to competences, but no consideration of their progression in the the curriculum or their assessment. Currently, the national priority is on the content knowledge in Science, although assessment instruments are requiring some longer answers that could encourage the development of *communication skills* and *the argumentation skills* associated with critical thinking about science.
Case 8 Germany
The curriculum framework documents in many of the states contain generic competences as goals of education, and in some the need to link them with subjects is stated but not in specific detail. Where Science is concerned, the competences of *scientific methods, scientific communication* and *socio scientific reflection* have been identified. Scientific communication is more than prose answers. It is to involve students in reflecting on the appropriate means for explaining scientific phenomena to someone else.

Case 9 Sweden
The aims of the new curriculum for the science include reference to *curiosity and asking questions*, *critical thinking (*about their own results, the arguments of others and different information sources), and *interpretation and production of science content in a variety of texts* (that can make use of different forms of aesthetic expression),

Discussion

The Curriculum as a whole

Each new major curriculum in Australia and New Zealand since 2000 has stated quite explicitly that some of these generic competencies are to be prominent features of the overall intended learning. In Sweden and in some German states there is also explicit reference to a number of similar competences. In Switzerland, England and Wales there is affirmation in curriculum discussions and reports of the importance of these competences, but they are less clearly associated with the subject curricula, where disciplinary content is clearly the current priority.

Only in Australia and Switzerland has there been an attempt to detail the progression of the generic competences through the stages of schooling.

The relation between Competences and the Science Curriculum

The ways in which the five different curriculum statements suggest Competence education should be related to Science education can be described as *Priority to Generic Competences, Unconstructed Relation*, *Overlayed Generic Competences,* and *Competences Reconstructed for Science* (see Table 1).

Priority to Generic Competences	Unconstructed Relation	Overlayed Generic Competences	Competences Reconstructed for Science
Tasmania, 2002 (ACARA, 2011)*	Victoria, 2006, Tasmania, 2004	Australia, 2011	Switzerland, New Zealand, Sweden, Germany

Table 1. Relations between Competency education and Science education

*It is of interest to note that early in 2011 ACARA developed a draft document on the generic capabilities that raised their inclusion in the national curriculum to a possible new level. Each capability is introduced with a Description and Rationale, and then listed as sub-capabilities for single or combined year levels . For Science this approach led to at least 80 opportunities for student activity for each 2 year stage. It, in effect, led to an alternative statement of intended learnings in science that prioritized the capabilities rather than the science. This approach was discontinued and In the final statement of for *Science* the simpler but vaguer approach of sprinkling symbols of the capabilities was used as described above in Case 4.

The expert reports from Finland, and England and Wales suggest that at this point of discussion there is an *Unconstructured Relation*, but those from Switzerland, Germany and Sweden indicate positions closer to the category, *Competences Reconstructed for Science.*

Gilbert's (2005) above concern that the demands of the Knowledge Wave would place too great an emphasis in curricular responses on skills to the detriment of knowledge now seems premature in the light of actual or possible developments since that time. Traditional science knowledge still dominates in each curriculum. Concern can, however, be expressed that those responsible for Science have not seized the opportunity presented by the competence demand to sufficiently re-consider in what ways it could benefit science education. In other words, how could the teaching science also include the active learning the competence movement advocates.

Such a reconstruction could start by preceding each competence with the disciplinary adjective, 'scientific'. At least two models are available for incorporating these in mainstream curricula for Science, thus establishing their place in category, *Competences Reconstructed for Science*, in Table 1.

The first model is the PISA Framework for science. The essential components are real world S&T contexts, scientific competences that involve both knowledge of science and knowledge about science (OECD, 2006).Since this framework is not intended for a whole curriculum about whether traditional science knowledge or scientific competences has priority. It simply indicates that the latter when included as a focus in a science curriculum requires context to betaken seriously if they are to have meaning.

The second model has been used by Labudde et al (2007) in the HamoS project in Switzerland. It is a three dimensional model with horizontal axes representing *the knowledge domain of the sciences*, and *a set of "skill" practices* (practical and intellectual that are used within science). The vertical axis is *years of schooling.* The priority for teaching and learning are the intersections where these skills are interacted with domain knowledge, that is, *a set of scientific competences*. The skills in the case of Switzerland are the eight listed above in Case 6..

Finally, there is now a rich literature of research studies on the teaching of scientific competences. More than two decades ago researchers in science education in many countries began to explore answers to the question, *What are scientific competences?* and *How can these be taught and learnt?* Ohlsson (1995) pointed out that each of *describing, explaining, predicting, defining, arguing, critiquing,* and *explicating* are epistemic for science thinking, and the classroom studies of some of these have now been well reported. That this research has been so weakly drawn upon by 21st C curriculum decision makers sharply questions whether their goal is about improved learning of science or about balancing the interests of other stakeholders that do not include the students.

A final point
One reason why science curriculum developers have found the question about scientific competences so difficult may be indicated by the fact that ***thinking*** is not present in the list of 61 metacognitive and metalinguistic verbs used in official science curriculum documents (Wilson, 1999). Despite a lot of effort and resources going into the production of the five curricula discussed, alas, a science curriculum that has *Science as a Way of Thinking* as an clearly articulated emphasis alongside S*cience as a Way of Knowing* is still some way off.

THE SPUTNIK REACHES ARGENTINA: THE CURRICULAR REFORM IN CHEMISTRY TEACHING (1956-1983)

Bruno Ferreira dos Santos[1]
[1]Departamento de Química, Universidade Estadual do Sudoeste da Bahia, Jequié, Brasil

Abstract: This paper attempts to reconstitute the introduction of Sputnik's reform in chemistry teaching in Argentina between 1956 and 1983. Based on several sources of historic data and taking into account the social and cultural contexts in which the knowledge about curricular innovation has passed through, I try to understand how a particular educational system processes a worldwide curricular reform. For that, I start from the presumption that the Argentinean reform is more than a simple transferring or importation of exogenous ideas and knowledge, but the result of their local interpretation. In this case, a net involving the scientific professional field, the educational state bureaucracy and multilateral organizations, such as OAS, produced a curricular reform towards the modernization of academic subjects that was slowly introduced and filtered by a settled scholar culture assuring the continuance of descriptive characters in chemistry teaching, particularly in relation to organic chemistry.

Keywords: chemistry teaching, curricular reform, Sputnik.

INTRODUCTION

The teaching of chemistry at schools, like other natural sciences, has undergone a transformation between 1960 and 1970, representing an unstoppable wave of renovation. The history of this curriculum reform has been told from different perspectives and with different purposes, often in studies that prioritize the national cases (Atkin, Black, 2003; Chassot, 2004; Rudolph, 2002). The changes in both curriculum and practices of science teaching throughout Latin America in this period are usually associated to the renovation movement that has its origins in the United States and was known as Sputnik reform, in a reference to the Soviet satellite launched to the space in 1957 - an icon of the space racing between Soviet Union and United States (Chassot, 2004; Merino, 1987). In the case of Argentina in particular there is a remarkable absence of studies to think over this curriculum transformation. This article seeks to contribute to cover, partly, this gap, directing its main question to the process of introduction of the reform in this country, specifically in the case of chemistry.

THEORETICAL FRAMEWORK

By studying a reform or a curricular innovation is important to take into account that the introduction of these school devices is never an exact transfer or a relocation of knowledge and ideas from one country to another, because these processes of change always involve local interpretations, resistances and confrontations that will subvert the original ideas. For some curricular and reform theories, it is important to understand how a particular national education system incorporates a worldwide reform to produce a "curricular standardization", acting like a "social refraction" to the global changes forces, as well as the tension among changes and continuance that follows any educational reform (Benavot et al., 1991; Goodson, 2008; Viñao, 2002). Furthermore, according to curriculum theory, decisions involving curriculum cannot be understood isolated from the contexts of economics, politics and ideology that characterize the larger society (Moreira, 2009).

This paper focuses on the introduction of changes into the curricular and practices of chemistry teaching at high schools in Argentina between 1956 and 1983 and its relationship with the American reform. It is implicit in this work that the historical knowledge can provide us with a better understanding of the current educational practices as well as the constant demands for reforms in scientific education. To approach this historic object, the study of the history of education recommends that, besides pedagogic doctrines, its authors and development, we should analyze the social and cultural contexts in which these ideas have taken place and eventually acquired some autonomy. The diversification of sources (documents, textbooks, syllabuses, interviews) is essential to unscramble the actual scenario, including its stabilities and ruptures.

METHODS

This article covers the period between 1956 and 1983 whose boundaries correspond to the fall of the first Perón government and the democratization process that ending the last authoritarian government, respectively. The beginning coincides with the developmental step and with the Argentinean "scientific spring", when occurs the creation of the National Research Council – CONICET (Cereijido, 2000). This research covers a period that includes governments of different ideologies and that switches democracy with military dictatorships, whose attitudes towards science and academic communities can be a stimulus or hostility and even violent persecution of their representants. This period is characterized by the presence of pedagogical ideals of modernization, based on educational planning and technology, whose premises are being questioned after 1983.

By approaching the Sputnik Reform in the Argentinean case, we are using methods and techniques originated in the field of research of the history of education, which include documentary research in archives, reading, classification and interpretation of different sources for the reconstruction of historic processes. Helpful in this case is the documentation from national and international conferences and symposia about chemistry teaching that occurred in the period mentioned above. Besides that, the chemistry textbooks can be used to trace the reform in a level more local and near to school teaching practices. Some personal testimonies helped me to collect information about the path of this reform, identifying important actors and institutions which were involved in the reform. For elaborating models of analysis and interpretation, some concepts used were from social studies of curriculum but also from more specific studies about chemistry curriculum (De Vos et. al., 2002; Goodson, 2008).

RESULTS AND DISCUSSION

During the second half of the fifties, the ideas about economic and social progress in Argentina were deeply attached to the development theory. According to this theory, the less developed countries should import capitals – both financial and cultural – in order to speed up their development. Therefore, social institutions like schools should be transformed by copying the models from developed countries such as United States. At the same time, Argentina tried to organize and encourage the scientific and technologic knowledge into the society, since they are supposed to play a key role in progress. In 1958, the government created a national council to the promotion of science and technology, CONICET. Moreover, the human capital theory which strongly associated the social and economic development with the investments in education reached the Latin America through several international conferences sponsored by multilateral organizations like UNESCO and OAS – Organization of American States, in the 60's. On the other hand, Argentina was highly differentiated from most of poor Latin countries once it had a consolidated educational system and low levels of illiteracy. Furthermore, the Argentinean citizens could celebrate one Nobel Prize in Physiology that would be followed by other two prizes in sciences a few years later.

The secondary schools in Argentina were also facing a fast expansion by that time and they had just introduced different modalities of technical and professional schools. Nonetheless, its curricular organization model and orientation for college studies were still the same of that from the beginning of the century (Dussel, 1994).

The syllabus of chemistry in 1956 (which would remain unchanged until 1978) is almost the same of 1901, when it had been divided into inorganic and organic chemistry in a two-year course. Most of textbooks were written in two volumes, being the first dedicated to inorganic chemistry and the second to organic chemistry. The contents were essentially descriptive: in the first year, teachers were supposed to teach about water, salts, hydrochloric acid, halogens, nitrogen and carbon; while in the second year, they should teach about hydrocarbons, alcohols, aldehides and ketones, glucids, amins and amides.

Over the early sixties, the Department of Science Teaching from CONICET has attempted to improve the science teaching by "promoting its updating and efficacy in order to offer a solid scientific basic formation and encourage young students, awaking or developing their skills to the studies of science and research" (Hernaiz, 1967, p. 1). Their efforts were addressed to training courses for high schools teachers majored in chemistry, physics, biology and mathematics. One of the goals of these courses was to give a new pedagogic orientation to the sciences teaching based on an updated methodology, which would assure both the knowledge transmission and the proper conception of the scientific method (Hernaiz, op. cit.). These general aims were quite similar to those of the American projects of science teaching like CBA and CHEM Study.

At the same time, the OAS organized several inter-American conferences about natural sciences and mathematics in different Latin American countries. The First Conference of Chemistry Teaching, a partnership with the American National Foundation of Science (NFS), took place in Buenos Aires in 1965. Institutions like Ford Foundation, Nuffield Foundation, the OECD and UNESCO were present as observers. Interchanges among the participants of this conference helped spread the ideas about the American CHEM Study and CBA projects, as well as the Nuffield Project from United Kingdom.

In 1968, the First National Symposium of Science Teaching occurred in the city of Cordoba. Its recommendations included the common objectives of science teaching and the specific objectives of chemistry teaching to be achieved by the Argentinean educational system. This initiative was followed by the First Meeting about Chemistry Teaching in San Luis, during November of 1970. These events, that occurred outside the federal capital, brought the reform in the science teaching to the inner parts of the country, trying to reach more teachers and persuade them to incorporate "the imperative necessity of updating the methods and contents to address properly all the scientific-technologic requirements of our times in this area, similarly to that occurred in other experimental sciences" (Guerrero, Bonelli, 1973, p. 3). But for that, a long way should yet be paced.

In this moment, the promotion of these changes had left the CONICET scope and was in charge of the new National Institution to the Improvement of Science Teaching - INEC – coordinated by the National Bureau of Education and Culture. The INEC recruited some academic professors from the University of Buenos Aires and the University of La Plata to act around the country as subjects to facilitate the updating of the chemistry teaching in the secondary schools (Argentina, 1972). With the sponsors of the OAS, the INEC followed one of the recommendations of the First inter-American Conference of Chemistry Teaching by promoting a course to in-service teachers about the new curriculum. Supported by the Bureau of Education, the INEC developed the "Proyecto 30", which begins to be applied, experimentally, in 1970 within the 4th and 5th years of some schools in the capital and provinces. The Proyecto 30 followed a structure of topic units that included modern chemistry theories and it was increasingly applied to a broader audience being its results evaluated until 1978. Based on it, the Bureau of Education incorporated new chemistry contents into the last two years of secondary school in 1978, to be obeyed from the next year on. The 14th edition of Héctor Sirventi´s textbook, a very popular chemistry textbook during the 70's, stated in its foreword that "the development of subjects meets all demands from Proyecto 30, nationally applied from 1979 on". According to the author, the new contents correspond to the project's recommendations. The previous division of chemistry into a two-year school course now is simply named Chemistry I and Chemistry II, where the first one encompasses General and Inorganic Chemistry, and its subjects are atomic structure, equilibrium and kinetics, while Chemistry II is nearly the same Organic Chemistry of the earlier curriculum.

In 1972, the UNESCO organized a Seminar about chemistry teaching in Montevideo, Uruguay. In this seminar were presented and discussed the contents of the syllabuses developed in the Proyecto 30. Professor Ariel Guerrero, chairman of this Seminar and main coordinator of Proyecto 30 made some considerations about the set of contents. For him, for example, some contents of Chemistry I like reaction mechanisms, isotopic tracers and complexes can be teached during Chemistry II. In his words, the contents constitutes "(…) a maximum, which offers a complex landscape of the chemistry since a fundamental point of view, with applications in the everyday life with the biologic and technologic, and that catches the student interest" (Actas Seminario UNESCO, p. 176, 1972). He also adverted that the separation in Inorganic and Organic Chemistry has just a pedagogic sense and it doesn´t represent "a cisma" in the chemistry, once the reaction mechanisms and chemical bonding constitute the unifying principles between both. Guerrero considers that the teacher may, at its discretion, waive topics that he thinks unnecessary or inaccessible. Nevertheless, it is preferable to teach all issues, as it is to present "a broad overview of chemistry" and, at same time, by applying the scientific method in its continuous cycle: "(…) formulating hypothesis, planning experiments; observing, measuring, interpreting…so it is advisable shorten many issues rather than eliminate them." (Actas Seminario UNESCO, 1972). In 1978, when the Bureau of Education approved the new syllabuses for the high school, it considers that these contents "show and meet the methodological approach recommended by the renewing of curricula in chemistry at the secondary level in all international conferences about it".

In the new syllabus of Chemistry I, General and Inorganic Chemistry replaces the old Inorganic Chemistry and its setting of contents follows those proposed by the American project CHEMStudy. In that way it is possible to understand what the Department of Secondary School had told about the Proyecto 30, which methodological approach had been put to the test during international conferences, in one of the mechanisms to produce educational isomorphism associated to the school curriculum (Dale, 2007). Notwithstanding, the new syllabuses keep the division between Inorganic Chemistry – now incorporating General Chemistry - and Organic Chemistry: although such division doesn´t represent the “cisma” to be avoided, it mirrors the survival of the disciplinar code of chemisty in the Argentinean curriculum (Santos, Porro, 2008). The continuance of this division will be feasible because it has adapted quite well to the technology of curricular organization, which distributes the contents of chemistry by two years since the beginning of the XX century. It also means the triumph of curriculum survey (De Vos et. al., 2002). At same time, this continuance allows the survival of the descriptive chemistry: this old feature of the chemistry´s syllabus will find a place exactly in Organic Chemistry and in the teaching of all its functions. By keeping this division, Guerrero and his co-workers look like want to ensure the complicity of teachers, leaving one disciplinary structure from the beginning of the century untouched.

CONCLUSIONS

According to Fumagalli (1999), the projects of curricular innovation and theoretic discussions about science teaching produced in United States and other central countries constituted the reference marks since Argentinean educators rethink the questions about science education in this country during the Sputnik reform. However, their influence over teaching practices was lean and it was confined to small circles of educators. But in the United States, the science teaching reform aimed to modify a curriculum filled up with progressive ideology, whose contents highlighted household technologies, towards a new model focused on the logic structure of sciences and the underlying construction of the scientific knowledge (DeBoer, 1991; Rudolph, 2002). In Argentina, a settled school culture assured the stability of a curricular structure organized in the beginning of the century, based on the division of academic sciences and thereby the descriptive features of contents remained throughout the organic chemistry taught in Chemistry II. The strictly centralized educational system in Argentina, with a national curriculum to be followed by all schools and organized by the state, demanded a long time up to the introduction of changes and the modernization of chemistry teaching. Argentinean scientists, differently from their American colleagues, were not involved in curricular issues, leaving this task to those professionals that agreed to follow the state bureaucracy and accepted the foreign influences from organizations such as OAS and UNESCO.

In an article that asks about the research and the future of chemical education John K. Gilbert and co-workers (2002) consider remarkable the fact that, despite huge differences between countries and cultures, the chemistry curriculum in all teaching levels be so similar around the world. The history of the introduction of Sputnik Reform in Argentina can display some clues to understand this convergence. Also it is possible through this study to determine the ways by which some continuances found their places in the new curricula.

BETWEEN SCIENCE AND CITIZENSHIP EDUCATION, THE CASE OF TRANGENESIS IN THE FRENCH BIOLOGY SYLLABUSES.

Magali Fuchs-Gallezot[1]
[1]UMR STEF - INRP -ENS de CACHAN (France)

Abstract: Transgenesis keeps on moving out of laboratories and industries into the public arena in the form of therapies, drugs, food products. This research, part of a PhD, deals with the way the scientific, medical, industrial and citizenship transgenesis practices are integrated in the French secondary school (pupils aged from 11 to 18 years old) biology syllabuses. It aims at describing the content and the organisation chosen for this school subject, reduced to its syllabuses. Identify aims, tasks, knowledge, reference and their consistency should especially allow to clarify if this teaching is thought by this school subject as science education or citizenship education.
The syllabuses analysed correspond to the last complete group of syllabuses elaborated for the school subject, "life and Earth sciences" (1996-2002).
The results show that the knowledge selected refers in majority to scientific practices while the tasks and supports refer to medical and industrial practices. The aims are often dual scientific and citizenship. A dual consistency can be identified: a scientific and a citizenship one. But if the scientific one is explicit (explicit connections between scientific knowledge, scientific aim) it is rarely the case of the citizenship one (the citizenship aims are rarely connected explicitly to knowledge or task). It suggests citizenship aim for transgenesis is present but secondary for this subject school whose aim would be first of all to ensure science education.

Keywords: school subject, French biology syllabuses, transgenesis, science or citizenship education, curriculum

INTRODUCTION

This research deals with the way transgenesis practices are integrated in the formal curriculum. Biotechnologies, especially transgenesis, keep on moving out of laboratories and industries into the public arena in the form of therapies, drugs, food products. It has and will have impact on the lives of citizens. Thus, transgenesis is a matter for scientific, industrial, medical and citizen practices.
As suggested by Martinand (1986) each of these practices have its own consistency which find expression in its different characteristics (intellectual and material tools, problems, social parts, knowledge produced). For citizens, transgenesis raises various socio-scientific issues with regards, for example, to ethics, to the level of acceptable risk and to the usefulness of the new products. For scientists, industrials or doctors, it brings other questions into play.
Insofar as transgenesis is a matter for science and citizenship education, it raises the question of how the French school subject dedicated to life and Earth sciences ("les sciences de la vie et de la Terre" other named SVT) have taken charge of it.

FRAMEWORK : HOW TO DESCRIBE A SCHOOL SUBJECT ?

A school subject is a complex and original elaboration taking into account different logics (political, institutional, social, philosophical, didactical) both for its elaboration and its implementation (Chervel, 1998). Our study only deals with the formal school subject, limited to its syllabuses. Only the didactical logic underlying the syllabuses elaboration is questioned. It aims at describing the content chosen and their organisation.
From a study on technology as a school subject, Lebeaume (1999) put forward a theoretical framework to contribute to school subject intelligibility. A school subject can be defined by

constructive and founding principles. Clarify these principles comes to identify the choices made about aims, task and supports, knowledge, reference and the consistency of theses different choices with one another for the whole school subject. The choices are all the more consistent as they refer to the same practice. The more it is consistent, the more its should allow pupils to better understand the practice taken as a reference.

PURPOSE AND RATIONALE

Our purpose is therefore to identify which choices have been made by a school subject, reduced to its syllabuses, for transgenesis as far aims, tasks, knowledge, reference and their consistency are concerned in order especially to clarify if this teaching is thought by this school subject as science education or citizenship education.

The research questions are :

- which aims, content (knowledge, tasks and supports) and reference have been selected for the different syllabuses for the different levels and "sections"?
- to which degree, aims, content and references are consistent?

METHODS

Data’s collection

The corpus is constituted by the syllabuses elaborated between 1996 and 2003 which is the last group of syllabuses describing a complete formal schooling from 6ème to Terminale (pupils aged from 11 to 18 years old). A new curriculum is being elaborated nowadays but it is not yet complete.

To deal with the analysis of a complete curriculum (Paindorge, 2007), a table collecting the knowledge, the tasks and supports and the aims related to transgenesis has been elaborated from the official secondary school’s syllabuses.

Data’s analysis

Each knowledge unit and task is compared to a characterization of different transgenesis practices in order to suggest a reference. The scientific, citizen, medical, industrial transgenesis practices taken as a reference have been characterized a priori.

The consistency of the various choices at a specific grade and through the curriculum is examined by connecting the knowledge, the tasks and supports, the aims and the implicit references.

RESULTS

Aims, contents and references selected for the school subject's different syllabuses

Transgenesis is present in the school subject syllabuses at five grades (cf. Table 1)

Table 1: grade and title of the part including transgenesis

Collège (6e, 5e, 4e,3e) (pupils from 11 to 15 years old) (compulsory school)
3e : "Human responsability : health and environment "
Lycée (2nde, 1ere, Terminale) (pupils from 15 to 18 years old)
2nde : "Cell, DNA and the unity of the alive" + themes in the choice
1ere ES (economic section) and 1ere L (literature section) : from genotype to phenotype : biotechnologies applications **1e ES**: "A natural resource : wood"
T S (scientific section) : "From genetics start to biotechnologies current stakes" (this part including transgenesis concerns only students who have chosen biology as a speciality)

Scientific practices have been selected in majority as a reference for knowledge.

The transgenesis scientific foundation is often called to mind (2nde, 1e ES/L). Several transgenesis aims referring to industrial and medical practices are evocated and are often connected to scientific knowledge: protein productions (1eES/L, TS), genetically modified organism (GMO) construction (1ère ES and TS), genetic therapy (TS). The environmental impact is only approached once in 3e and refers to citizenship practices for it is connected to the idea of watchfulness towards biodiversity.

Medical and industrial practices have been selected in majority for tasks and supports.

Tasks and/or supports referring to transgenesis are proposed for almost all grades. The tasks and supports selected aim at studying transgenesis through different examples: GMO tolerant to pesticide (TS), improvement of quality for wood industries (1ère ES), production of drugs (1ère ES/L/TS). Only one task and support refer clearly to citizenship practice. They aim at studying transgenesis impact on the environment from the societal angle (by analysing documents dealing with the problems associated to plant GMO (TS)).

Scientific and citizenship aims are associated with transgenesis.

In 1e ES/L and TS, citizenship aims are closely associated with scientific aims: the reflexion must be based on scientific knowledge. In 3e and 2nde the aims are either citizenship (3e) either scientific (2nde).

Consistency of these choices

An example : analysis of the consistency of the choices for the part taught in 1eES/L : "From genotype to phenotype, biotechnologies applications".

The scientific aim (to understand the genetic information expression) and the knowledge (transgenesis lay on genetic code universality) referring to a scientific practice are consistent and refer both to science. On the other hand, the task referring to an industrial practice (production by transgenesis of drugs) and the citizenship aim (to tackle a critical reflexion on genomes studies and biotechnologies applications including transgenesis) are not clearly connected to anything in terms of reference. The main consistency is thus scientific. The task referring to industrial practices is in fact to the scientific aim's service. The industrial reference is hence hidden. At last, consistency between the citizenship aim, a reference to citizenship, the knowledge referring to science and the task referring to industry remains implicit in the syllabus. A citizenship consistency is thus possible but not explicit.

Transgenesis is for this syllabus, rather part of a science education than a citizenship education.

A dual consistency (scientific and citizenship) can be identified for the a majority of syllabuses. The explicit reference in syllabuses of knowledge (K), task (T), aim (A) to science (S) or citizenship (C) is indicated for the different grade in table 2.

Table 2 : explicit reference to science or citizenship of syllabuses' content and aims

Reference to	**3eme**	**2nde**	**1ere ES**	**1ere L**	**TS-speciality**
science		**KTA**	KA	**KA**	**KA**
citizenship	**KA**		A	**A**	**TA**

Table 2 shows that, for this school subject, the consistency thought in syllabuses is above all scientific : most of knowledge refers to scientific practices and are consistent to scientific aims. The citizenship consistency is always implicit except in 3e and TS where a knowledge (3e) or a task (TS) are referring to citizenship practice and can be explicitly connected to the citizenship aim.

CONCLUSION AND IMPLICATIONS

The knowledge selected refers in majority to scientific practices while the tasks and supports selected refer to medical and industrial practices. In this way, it appears that for transgenesis school subject is thought as original elaboration gathering elements taken from different practices. This raises the question of which image of these practices this school subject contributes to build. To which degree, this school subject reduced to its syllabuses allows to understand these practices, their different logics and stakes.

Furthermore, transgenesis is connected in the syllabuses to a genetic teaching which is part of a determinist vision of genetics especially in 3e and 2nde (Fuchs-Gallezot, 2009).

Otherwise, the aims are often dual scientific and citizenship. Citizenship taken as a reference is always a citizenship based on rationality (Tutiaux-Guyon, 2006). The point is to show how scientific knowledge could contribute to better understand different socioscientific issues.

A dual consistency can be identified: a scientific and a citizenship one. But if the scientific one is explicit (explicit connections between scientific knowledge, scientific aim) it is rarely the case of the citizenship one (the citizen aims are rarely connected explicitly to knowledge or task). It raises the question of the difficulty for teacher to identify in syllabuses the dual scientific/citizenship consistency and to implement such a complex organisation.
It suggests citizen aim for transgenesis is present but secondary for this subject school whose aim would be first of all to ensure science education.

SCIENCE IN THE IRISH TRANSITION YEAR: THE PUPIL EXPERIENCE

Sarah Hayes[1] *& Peter Childs*[1]
[1]NCE-MSTL & Department of Chemical & Environmental Sciences,
University of Limerick, Ireland
E-mail: Sarah.Hayes@ul.ie

Abstract: This study is concerned with the Irish Transition Year Programme (TYP). The TYP is an optional year in the second level Irish education system, which falls between the junior cycle and senior cycle. The year is curriculum-free, allowing schools the autonomy to design their own curriculum and syllabi for the year. This study is part of a larger one which aims to investigate the place of science in this year. The study tried to achieve a holistic view of science in this year, and as such investigated science in Transition Year from the perspective of pupils, teachers and students. This paper presents some results from the pupil perspective, in particular examining the pupils' experiences of science in the year. Previous work has shown that teachers are not using the year to design their own curriculum, but are relying on the senior cycle science curricula. This study has indicated that the teaching methodologies used by the Transition Year science teachers are significantly different to those used in teaching junior cycle science. However, the results of this study indicate that this year has little impact on pupils, and many still choose not to take up science to senior cycle, particularly the physical sciences.

BACKGROUND, FRAMEWORK, AND PURPOSE

The Irish second level education is broken into two cycles: the junior cycle and the senior cycle. Both of these cycles culminate in a terminal state examination. Between the two cycles is a one year programme known as the Transition Year Programme (TYP). This programme is an optional one year programme, which schools are not obliged to offer and if offered, pupils are not obliged to take it (Department of Education 1993). The year was originally introduced in the1970s in recognition of:

- The need to encourage personal and social development;
- The right of all students to a six-year post-primary education;
- The fact that Irish children leave second level school at a younger age than their European counterparts;
- The failure rate at third level;
- Employment prospects at that time.

(Transition Year Second Level Support Service 2006)

These issues, which led to the introduction of the Transition Year, are currently still relevant to Irish pupils. Over the last 5 years over three-quarters of second level schools offer the TYP, and over half of pupils have taken the year. The TYP has long been hailed as a particularly innovative and unique year. To date no study has investigated how this curriculum-free year is being utilised in terms of science teaching. The TYP offers teachers a rare opportunity to teach science in a relevant, context-based manner, appropriate to their individual pupils. The Irish education system has been noted to be highly centralised and standardised and typically uses traditional, didactic teaching methods (Forfás 1999, p. 20, Smyth *et al.* 2004, p. 7). This study has evolved to address the lack of information currently available on the place of science within the TYP. This paper seeks to investigate the experiences of pupils taking science in the TYP.

METHODOLOGY

A number of research questions were developed in order to define the parameters of the study. The specific research questions to be answered in relation to the pupils' experiences of science in the Transition Year Programme are as follows:

- *What are pupils' experiences of science within the Transition Year?*
- *What impact, if any does taking Transition Year sciences have on pupils' decision to take a science subject at senior cycle?*

This study is part of a larger PhD study, utilising a dual methodological approach. A quantitative approach was taken for this element of the study, though the study as a whole incorporates a mixed method approach. A pupil questionnaire was developed both for pupils at the end of their TYP experience, and pupils at the end of their Junior Certificate science experience.. The questionnaire was designed to explore attitudes and feelings towards science. It also sought to identify how the science in the Transition Year was being utilised in the schools that offer the programme. A review of previous research conducted in the area of the Transition Year and Transition Year science provided the basis for the design of the instrument (Smith and Matthews 2000, OECD 2004, Smyth *et al.* 2004, Darmody and Smyth 2005, Regan 2005, Jeffers 2007, Childs *et al.* 2010, Matthews 2010, OECD 2010). Both questionnaires were designed in three sections. The three sections in the Transition Year pupil's questionnaire consisted of 'general information', 'Transition Year and Transition Year science', and 'subjects I plan on studying for my Leaving Certificate'. Similarly the Junior Certificate science pupil's questionnaire consisted of a section on 'general information', a section on 'the Junior Certificate and Junior Certificate science' and 'subjects I plan to study for my Leaving Certificate'.

In total 25 schools were selected which offered the TYP, and 5 schools which did not offer the TYP. These schools were randomly selected from two databases, one listing the schools which offer the TYP, and one listing the schools who did not offer the TYP. Both groups of pupils were at the same educational stage as they were about to move into the senior cycle. Schools were contacted by letter, which was followed up with a phone call in order to get agreement from the schools to take part in the study, and finally the questionnaire was sent to 21 schools who agreed to participate in the study. Of these 16 schools (3 non-TYP schools and 13 TYP schools) returned the questionnaires, giving a response rate of 71.4%. In total, 319 pupils responded throughout the 16 schools. The responses of these questionnaires were analysed using PASW (Predictive Analytics Software), version 17.0.

RESULTS

Two groups of pupils (N = 319) were surveyed in 2009 using the two different instruments described in the methodology. In the first group, the pupils surveyed (N = 277) were administered the questionnaire at the end of their Transition Year, and are attending a school which offers the Transition Year programme. Of the 277 TYP pupils surveyed 121 (43.7%) were male and 156 (56.3%) were female. Pupils' median age was 16 (n = 218, 78.7%), though a small percentage of the cohort were 15 (n = 36, 13.0%), and 17 (n = 22, 7.9%), with one pupil aged 19 (0.4%). The majority of pupils (33.3%) took the year because it was compulsory in their school; however, 21.8% of pupils took the year as they felt it would be an opportunity to mature, other (11.5%) felt the year would allow them a break from studying and the pressure of the standardised system. The second group of pupils (N = 42) were at the

end of their Junior Certificate programme in non-TYP schools. This group was the control group for comparison against the TYP group.
Science may be offered to pupils in a wide variety of formats in the Transition Year or it may not be offered at all. Science is not compulsory at any level in the Irish second level system including the TYP. Results show that 60.0% of Transition Year schools offer the physics in the TYP, 51.6% offer chemistry, and 64.4% offer biology and some offer a combined science taster (35.6%). When the TYP pupils were compared to the non-TYP pupils, there were no differences between their attitudes towards science. Both groups ranked science as their 5th favourite subject. There were also no marked differences between pupils' levels of enjoyment or interest of science. Overall, non-TYP pupils were more positive about their experiences of junior cycle science, in comparison to the TYP pupils' retrospective look at their experiences of the subject. This was not a significant difference. However, there were differences in how the subject appeared to be taught. The tasks in the TYP were significantly different ($p < 0.05$) to those that non-TYP pupils completed in their science classes. Junior Certificate science appeared to consist mainly of 'traditional' activities such as reading, answering questions from and writing in their science book, doing calculations and having regular written and oral tests. TYP pupils spent more time taking part in group work, having pupil presentations and visiting speakers, using the computer and internet, and entering science competitions. As to whether the TYP influenced the uptake of science subjects to senior cycle, a significant number of non-TYP schools did not offer physics or chemistry and there was little difference between the percentages of students who took these subjects. However, a significant number of pupils coming from the TYP schools chose to take biology, which was offered at senior cycle in all schools.
A wide variety of subjects were offered to the pupils in the TYP. Figure 1 illustrates the subjects that were offered to the pupils. It is worth noting that while a wide variety of subjects were offered to pupils, the subjects were not offered uniformly to pupils.

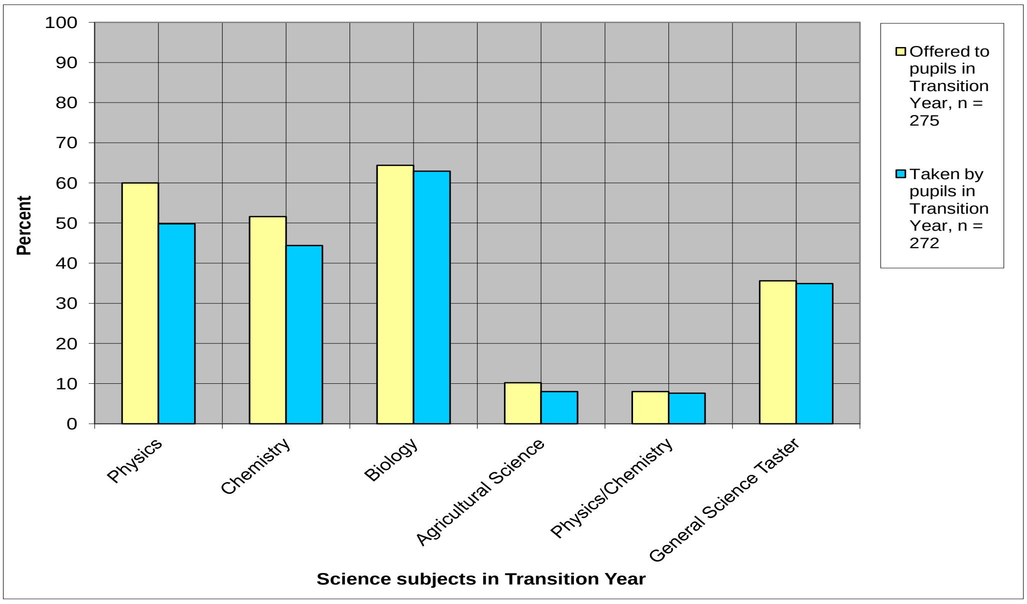

Figure 1: The science subjects offered to and taken by TYP pupils.

As illustrated in Figures 1, there is a significant mismatch ($p < 0.001$) between the science subjects offered in the TYP and those taken by the pupils.
The number of practical classes per week in TYP science classes was examined. Although most pupils have one or more practical science classes per week, 15.8% of pupils have either no practical classes or less than one per week.

The study also investigated the range of activities that pupils were experiencing in their TYP science classroom, and compared this to a more traditional Junior Certificate science class.

In line with Transition Year guidelines, pupils rarely or never do activities such as writing in (43.8 %) or answering questions from (77.9%) their science text book, or reading from it (74.6%). Practical activities, such as working with apparatus or materials (82.3%), carrying out experiments (83.8%), doing project (75.1%) and group work (91.6%) were all experienced often or sometimes by pupils. However, activities central to the development of communication skills, scientific literacy and critical thinking in science, such as having pupil presentations (66.2%), debates (83.0%) and taking part in activities such as the BT Young Scientist, SciFest or Science Fairs (63.2%) were all experienced rarely or never. Activities, such as visiting scientific industry (80.8%), going on field trips (80.8%), listening to visiting speakers (60.5%), or attending seminars (83.6%), which would allow pupils more insight into the everyday contexts and the various types of science-related jobs, were also rarely or never experienced.
However, when the TYP pupils' experiences of the frequency of these activities were compared with the non-TYP pupils, using Chi square testing, some significant differences were noticed as indicated in Table 1 below.

Table 1: The differences between non-TYP and TYP pupils in the frequency of activities in science class.

Type of Activity	p-value	Pupils who experiences the activities most frequently
Writing in your science workbook/practical copy	0.001***	Non-TYP
Answering questions from your science text book	0.000***	Non-TYP
Listening to the teacher talk about topics	0.496	Non-TYP
Reading from a science text book	0.000***	Non-TYP
Having discussions about science	0.806	TYP
Watching the teacher use apparatus to demonstrate ideas	0.583	TYP
Working yourself with apparatus/materials	0.016*	TYP
Doing calculations	0.001***	Junior Certificate
Carrying out experiments	0.075	TYP
Doing project work	0.239	TYP
Doing group work	0.000***	TYP
Having pupil presentations	0.003**	TYP
Having debates	0.280	TYP
Watching T.V./DVDs/Videos on scientific phenomena	0.000***	TYP
Using a computer	0.000***	TYP
Using the internet	0.000***	TYP
Going on field trips	0.001***	Non-TYP
Visiting industry or scientific businesses	0.177	Non-TYP
Listening to visiting speakers	0.001***	TYP
Attending seminars	0.284	Non-TYP
Having written tests	0.000***	Non-TYP
Having oral tests	0.000***	Non-TYP
Work Experience	n/a	n/a
Taking part in activities such as SciFest, BT Young Scientist, Science Fairs etc.	0.000***	TYP

Significance levels: *p< 0.05, ** p<0.01, ***p<0.001

The data in Table 1 clearly indicates that non-TYP pupils experience more traditional activities in their science classes. TYP pupils appear to have their science classes more supplemented with access to resources and slightly less traditional teaching and learning techniques. Traditional assessment techniques are also experienced less frequently by TYP pupils. TYP pupils have significantly more experiences of general practical activities, when compared to the non-TYP group. TYP pupils also carry out experiments with more frequency than their non-TYP counterparts, though this is not a significant difference.

Overall, pupils enjoy their Transition Year science class. This is also true for non-TYP pupils in their science classes. Due to the non-parametric nature of this data the median was used as the measure of centrality, and Mann Whitney tests were conducted in order to compare the differences between the groups. When compared with non-TYP pupils' enjoyment of their Junior Certificate science class there were no significant differences ($p = 0.963$), and a reported median value of 2.00 for both groups. These results were also true for both male and female pupils, with both equally enjoying their Transition Year science class (*Mdn* = 2.00, $p = 0.716$). This indicates that the majority of pupils enjoy their science class, regardless of the year they are in.

The majority of pupils plan to take biology in the senior cycle. A slightly higher proportion of pupils (71.6%) indicated that they planned to take this subject in response to this question, than in the previous free response question (66.1%). It is worth noting that biology is the only science subject to be offered to pupils in every school surveyed. Results between the TYP pupils and the non-TYP pupils and gender were once again compared in Chi square tests. Similar to the previous results discussed, biology was the only science subject that a significantly higher proportion of TYP pupils planned to take in the senior cycle (71.6%). Only 55.3% of non-TYP pupils planned to take this subject, and this difference was considered to be statistically significant ($p = 0.023$). Physics shows similar trends to the previous results: more TYP pupils (18.0%) plan to study the subject than non-TYP pupils (14.6%), but this difference is not statistically significant. A significantly ($p = 0.001$) higher proportion of non-TYP pupils (29.3%) planned to take chemistry, and only 16.2% of TYP pupils indicated that they planned to take the subject. A greater proportion of non-TYP pupils (35.0%) planned to take agricultural science than their TYP counter parts (11.5%), but this is not significant. Biology has a significantly ($p = 0.001$) higher proportion of female pupils planning to take the subject; this is also true for chemistry, but is not significant. The proportion of male pupils (29.8%) planning to study physics for the senior cycle is significantly ($p = 0.003$) higher than of female pupils (13.2%). Agricultural science also experiences this trend, but not significantly so. The pupils who are planning to take one or more of the various science subjects cited various reasons for their decision, such as planning for future career and potential to achieve good grades.

Over all Transition Year does not appear to overwhelmingly encourage or discourage pupils to take a science subject in the senior cycle, with only 49.8% of pupils stating that the year has encouraged them to take up a science subject in the senior cycle. When Chi square tests for gender were performed, it was found that female pupils are significantly ($p = 0.014$) more encouraged (57.8%) by the Transition Year to take up a science subject in the senior cycle than male pupils (42.6%).

DISCUSSION AND CONCLUSION

A wide variety of curricula and teaching and learning activities are present in Transition Year science classrooms around Ireland. The research questions, which guided this aspect of the overall study, are discussed here in relation to the findings.

- *What are pupils' experiences of science within the Transition Year?*

Pupils agree that Transition Year science classes are overall an enjoyable positive experience. Their science activities vary in nature from those carried out at Junior Certificate level.
The experiences of the TYP pupils differ greatly from those of the non-TYP pupils, with respect to how science is treated: TYP pupils experience more practical classes per week than their non-TYP counterparts. A contributing factor in this may be the tight curriculum constraints experienced in the study of Junior Certificate science. Not unexpectedly, there is also a clear disparity between the types of activities carried out by pupils in the two types of science classrooms.TYP have more positive experiences in their science classrooms: the activities that are carried out more frequently than their non-TYP counterparts are conducive to discovery learning (Bennett 2003, p. 75), active learning (Kyriacou 1998, p. 39), problem-based learning (Kelly 2000, Bennett 2005) and context based learning (Campbell and Lubben 2000, p. 240, Schwartz 2006), all of which has implications for improving pupils' understanding of Science (Adey *et al.* 1989, Johnstone 2000, Monk and Osbourne 2000, p. 161, Reid 2008).

- *What impact, if any does taking Transition Year sciences have on pupils' decision to take a science subject at senior cycle?*

While a higher proportion of TYP pupils than the national average planned to take up a science subject at senior cycle, the year did not encourage them to make this choice. Results indicated that female pupils were significantly ($p = 0.014$) more encouraged, by the Transition Year, to take up a senior cycle science subject. Those pupils who were encouraged by the Transition Year to take a senior cycle science subject had a higher planned uptake of physics, chemistry and biology than those who had not been encouraged to take a subject by the Transition Year. There was a significant association between whether or not the Transition Year had encouraged pupils to take a science subject in senior cycle and them deciding to take one. A significant positive association was found between pupils who enjoyed their Transition Year science class and those who were encouraged to take a Science subject by the year. Therefore, perhaps when the Transition Year science class is taught in an enjoyable fashion it does encourage uptake of science subjects for Leaving Certificate. The findings of this study echoes other studies (Milner *et al.* 1987, Smyth and Hannan 2002, Cleaves 2005, Lyons 2006, Smyth and Hannan 2006, Reardon *et al.* 2010), indicating that pupils are driven by the examination culture, and choose subjects that they feel that they will do well in and will aid them in their future. That is not to say that interest and enjoyment does not play a part in the pupils' decisions, but it is not the principal factor.
This study indicates that the Transition Year is a worthwhile and positive endeavour, which is failing to achieve its full potential in terms of pupils' experiences of science in the year.

DEVELOPMENT OF A NEW INTERDISCIPLINARY ADVANCED SCIENCE COURSE: NATURE, LIFE & TECHNOLOGY

Berenice Michels[1], Jenneke Kruger[1] and Harrie Eijkelhof[2]*
[1] SLO, Enschede
[2] Utrecht University
[*] Corresponding Author: SLO, Postbus 2041, 7500 CA Enschede, the Netherlands

Abstract: In order to motivate senior secondary students and teachers to get acquainted with new developments in science and technology a new course Nature Life & Technology (NLT) was developed between 2006 and 2011. This elective course deals with interdisciplinary issues covering a broad field of science and technology. In this paper the development process of this course is evaluated. Factors which contributed to its success were: cooperation between school teachers and science experts in developing the modular learning materials, strict quality control of these materials, agreements with school administrators about teaching conditions and a national network of regional support centres.

Keywords: curriculum development, interdisciplinary, upper secondary, science teaching, team teaching

BACKGROUND, FRAMEWORK AND PURPOSE

Across the world science curricula are in the process of revision or have recently been renewed (e.g. Atkin & Black, 2007; Millar, 2006; Ogborn, 2005; Parchmann et al., 2006; Wei, 2009). Many new initiatives in science education focus on pupils in the ages of compulsory education, primary and junior secondary, however students make decisions about their future influenced by their experiences in senior secondary school. Requirements of secondary education are often such that teachers in senior science courses have little time to deal with modern topics. In addition, modern science topics are often interdisciplinary while senior courses in science are usually monodisciplinary and teachers usually lack expertise and confidence to properly teach these topics. So in order to promote teaching interdisciplinary topics which offer students and teachers new insights into current developments in science and technology, a new elective course "Nature Life and Technology" (NLT) was created. NLT is to be taught to senior secondary students in science streams, in addition to the regular courses in physics, mathematics, chemistry and biology. Depending on the type of school students should spend 320 or 440 hours to study this course (including school and home work). Schools are free to offer the course which is assessed by a school based examination.

RATIONALE

Such advanced interdisciplinary curriculum initiatives at the senior secondary level are not common across the world and require large efforts in the fields of development of study programme, course materials, teacher training, school organization, cooperation with the world of science and technology, quality assessment and communication with parents and students. Specific challenges for the development of NLT were:

1. in the Netherlands no experience was available with this kind of courses at senior secondary level: no teaching and assessment materials, no teacher training and no experience with interdisciplinary team teaching at this level;
2. in order to make a successful start with the course in Dutch secondary education the start of the course should be in line with a structural revision of senior secondary education, i.e. September 2007, while the decision to create the course was made mid-2005. This created high pressure on the development of the course.

In this paper we will evaluate these efforts over the last five years guided by the central question: What measures were successfully taken during the curriculum development and implementation process to enhance the advanced and interdisciplinary character of NLT?

METHOD

A Steering Committee NLT was created early 2006 to take care of development, introduction, monitoring and evaluation of the first five years of NLT. The approach was to define the aims and create an outline for the new course, to develop a study programme as well as course materials (consisting of modules) and to stimulate and support schools to implement the new course (Krüger and Michels, 2007). In the period 2007 – 2010 the development and implementation of NLT was monitored by several studies, both quantitative and qualitative ones (e.g. Kuiper et al., 2010).

RESULTS

The goal of NLT is to make the natural sciences and technology more attractive and to create coherence in the different subjects of the sciences. In more detail the following aims were defined (Steering Committee NLT, 2008):

- to offer both a broader and more in-depth study programme for science and mathematics;
- to enable students to get familiar with a wide range of follow-up studies and professions;
- to let students experience the importance of interdisciplinary coherence in the development of science and technology;
- to create a closer connection between science education and new developments in society, science and technology, in interaction with higher education, research institutes and the business community;
- to offer more choices to teachers and students in the sciences at school;
- to make a contribution to permanent innovation of science education.

In order to cope with the limited amount of time a parallel course of development took place, i.e. the course outline and study programme were written in the same period in which the development of course materials started. The study programme was formulated in cooperation with teachers and students from tertiary education. The formulations were chosen very broadly so that in principle any topic relevant to a science study or profession should fit in and could therefore be developed into a module.

In order to involve teachers and schools and to ensure quality of content and didactical approach, for each module a writing team was formed which consisted of some science and mathematics teachers and an expert from higher education. In order to ensure quality of the teaching material, criteria were formulated and made known before development started. Each writing team followed a strict cyclic process of development, piloting and evaluation and revision (Eijkelhof & Kruger, 2009). Only modules which met the criteria were certified by the Steering Committee for use in NLT lessons.

Considering the lack of experience with interdisciplinary courses in Dutch education, the Steering Committee NLT formulated some requirements for those schools which wanted to implement NLT. Examples of requirements are: NLT is taught by a team of at least three teachers qualified for upper secondary with different specialism (mathematics, physics, chemistry, biology, earth science); school administrations provide means (time and finance) to these teams for professional development and preparation; schools make use of certified modules and contribute to evaluation activities. Furthermore it is encouraged that school administrations offer sufficient practical facilities; such as lab and computers and a suitable timetable to teach NLT and that students get opportunity to learn from external sources, i.e. universities, polytechnics or industry.

NLT aims to promote insight into current developments in science and technology and to assist students in a realistic orientation on a career in those fields. In order to fulfil these aims it is important to have structures in which long term and meaningful contacts exist between secondary and higher education. In 2008 the project team NLT therefore started stimulation and coordination of a national network of Regional Support Centres NLT. A Regional Support Centre consists of at least one university, one polytechnic and a number of secondary schools in the region. They form a network to support and improve teaching and learning of NLT. The universities and polytechnics also take care of maintenance and updating of the certified modules.

Table 1
Examples of Topics of Certified Modules

Pre-college level	**Pre-university level**
Air pollution and aerosols	Artificial kidneys and membranes
Alcohol and traffic	Bioinformatics
Biotechnology	Biosensors
Epidemics in agriculture	Brains and learning
Forensic science	Chemical cooking
Glass horticulture and energy	City climates
Glue and adhering	Climate change in the north pole area
Heart diseases	Cystic Fibrosis
Making and tasting bread	Food or fuel: 2nd generation biofuel
Medical imaging	Heart diseases
Optimizing achievement in sports	Holograms
Surviving in the international space station	Hydrogen cars
Sustainability in schools	Medicins: from molecules to humans
Sustainable soil management	Moving continents
User friendly technology in health care	Nanoscience and technology
Using GIS for safety	Nuclear fusion
Water purification	Room for rivers: redesigning river forelands to avoid flooding
Zero-energy house	Stellar course of life

During 2007 – 2011, 66 modules were developed and certified by the Steering Committee NLT. Teachers from 96 different schools were involved in developing modules and teachers from 54 other schools tested the materials, scientific experts came from 10 different universities, 12 colleges and 25 other institutes, such as research institutes and industry. The total number of developers was 436. Table 1 shows some examples of topics covered by these modules.

From the analysis of registration data it is found that in almost all NLT teams a biology (97%) and a physics (96%) teacher are involved, followed by chemistry (89%) and mathematics (75%). In 45% of the NLT teams a geography teacher is present.

In September 2010 the number of registered NLT schools was 230, i.e. 44% of all senior secondary schools in the Netherlands. Schools mainly use the certified modules.

CONCLUSIONS AND IMPLICATIONS

As might be expected from such an innovative course as NLT several problems were faced during the development and implementation. There was a lack of suitable study and teaching materials, in combination with the urge to meet high standards in content and pedagogy in order to make such a new course feasible and attractive for students and teachers and approved by science experts (Eijkelhof & Kapteijn, 2000).Teachers in secondary schools lack sufficient knowledge about current developments in science and technology and tend to focus strongly on the teaching culture in their own schools; scientists appear to overestimate the knowledge of high school students and to miss the ability to design suitable student activities. The formation of writing teams existing of teachers from at least two different schools and science experts, combined with the use of a strict quality assurance procedure, including piloting in independent schools and collecting expert reviews proved a successful strategy.

For many schools the requirement to form teaching teams was quite new; it resulted in new forms of cooperation between teachers and in novel ways of time tabling.

Scientists usually are highly involved in their own research and teaching in higher education. Nevertheless almost all universities and many polytechnic colleges cooperated in a variety of ways in designing materials and supporting schools during teaching. Possibly because it was in their interest to make their field of expertise accessible to prospective students or simply because they enjoyed contributing to development of teaching materials on topics in which they were highly and enthusiastically involved as professionals.

In our view a course such as NLT is relevant to educational systems in other countries for various reasons:

- Lack of enthusiasm for science and technology careers is an issue in many countries and might be reduced by (re)connecting school science to developments in research institutes and industry.
- Interdisciplinary topics often have global implications which could well be addressed in the course materials.
- This type of course offers opportunities for teachers for life long learning in their own and neighbouring field of expertise.

Therefore we would be highly interested in developing a network of curriculum projects with similar aims. It is time to share materials and good practices in this field.

[3]Emeritus Professor, Kobe University, Japan

Abstract: Since the United Nations Decade of ESD commencement, science education for ESD has manifested a new energy. While the Cabinet Office of Japan notes that one of the objectives of ESD is to raise public awareness of the need for SD, many students are not conscious of this necessary growth path. Hence, this study seeks to develop a pilot programme with the educational objective of increasing SD awareness. As a result, it appears that students found concrete issues and subjects of SD in everyday life by the end of the programme, while their knowledge of this subject was poor at the beginning. Moreover, the students came to understand SD-oriented issues as familiar occurrences in their daily lives. To conclude, it is suggested that a positive outcome was obtained by the pilot programme in promoting student awareness of SD. In addition, it is pointed out that activities of SD and ESD in Japan have mainly progressed in environmental aspects for students.

Keywords: Education for Sustainable Development (ESD), Higher Education, Public Awareness, Practice and Evaluation

INTRODUCTION

The United Nations Decade of Education for Sustainable Development (ESD) began in 2005 (UNESCO, 2005). Since its commencement, science education for ESD has manifested a new energy in Science Education (Fensham, 2008). For instance, in Japan, ESD has become an important theme that has attracted the attention of the Japan Society for Science Education (see, for example, Abe, 2007; Nogami, 2010). Ogra (2008) suggested that practical programme development is expected in consideration of the local context in ESD. The importance to consider the local context are also described in assessing scientific literacy as PISA 2006 (OECD, 2007) . Furthermore, the educational projects of universities and colleges are flourishing (see, for example, Dawe et al., 2005;Itoh et al., 2008). ESD focuses on a range of subjects such as the environment, human rights, and health and safety (UNESCO 2005). Therefore, its educational objectives and content may differ by country and area.

What is required for ESD in Japan? The Cabinet Office of Japan (2008) notes that one of the objectives of ESD is to raise public awareness of the need for sustainable development (SD). However, many students are not conscious of this necessary growth path, since both SD and ESD are new social concepts.

RATIONALE

The Cabinet Secretariat of Japan indicates, ‘As an outcome of ESD, it is expected that people can change unconscious decision-making into concrete social action. It is also a key to reform education and the value norm (2008)’, and ‘ESD is the education for every people to recognize that they live in the global world, and have the relationship with the future generations and environment (2009)’. UNESCO (2009) calls attention to the necessity to 'raise public awareness of the concept of sustainable development'. Burns et al. (2003) define public awareness of science (PAS) as 'a set of positive attitudes towards science (and technology) that are evidenced by a series of skills and behavioural intentions'. In sum, awareness of SD may be the key issue for an ESD programme. However, few studies clarify student awareness of SD. What is SD for Japanese students? Do they know about SD, and can they identify it and the issues related to it in their surroundings? In this regard, it is important to raise the SD awareness of students who will lead society in the future. Incidentally, it is indispensable to use an effective information and communication technology (ICT) tool when developing a scientific educational programme (Fensham, 2008). Hence this study seeks to develop a pilot programme with the educational objective of increasing SD awareness and to employ an effective ICT tool in this process.

PURPOSE AND PROCEDURE OF THE STUDY

Purpose

In this study, the design and practice of a pilot SD awareness programme for college students is first outlined. Then, the results of the pre-tests and post-tests of the students' SD awareness are revealed in terms of the evaluation of the pilot programme. In addition, characteristics of concrete SD images among the present students are considered based on the programme contents.

Design of the Programme

The programme was performed 15 times in 90-minute weekly sessions. The contents of the programme included (1) introduction and lectures for five weeks, (2) class-work and fieldwork by students for five weeks, and (3) student group discussions and a summary of the programme for five weeks.

The 'ClipGallery' was developed by one of the authors as the effective ICT tool of for the fieldwork in the activity of (2) (Takenaka et al., 2005). The system configuration of the ClipGallery is shown in Figure 1. Students took photographs of SD-oriented issues on their mobile phones and sent them to the ClipGallery. They discussed 'Of what', 'Where', and 'Why' they took the photographs within their groups.

Period of Investigation and Target Students

Period: 20 April 2010–27 July 2010 (pre-test: 27 April; post-test: 27 July)

Target Students: 34 students in Kobe College, Japan

Contents of Investigation for Students' Awareness of SD

(1) Word association (pre-test and post-test)

Key word/phrase: 'Sustainable development is'
Time to answer: 5 minutes

(2) Multiple questionnaires in four scales (pre-test and post-test)

'4: strongly agree'; '3: slightly agree'; '2: slightly disagree'; and '1: strongly disagree'

(3) Photographs in the ClipGallery by students

Students write (a) the title-'Of what', (b) the place-'Where' and (c) the reason 'Why' to the photographs that they took in the web list of the ClipGallery.

RESULTS & IMPLICATIONS

The results of ‘Word association’ and ‘Multiple questionnaires’ are respectively shown in Tables 1 and 2. Using ‘Word association’ (Table 1), it appears that students found concrete issues and subjects of SD in everyday life by the end of the programme, while their knowledge of this subject was poor at the beginning. For example, the number of association words is significantly increased in the post-test. The same trend is clearly shown in the average, the minimum and the maximum number of words per person. From Table 2, we find that the scores of the post-test are higher for almost all questions than those of the pre-test. These facts reveal that students gained a concrete sense of SD after their fieldwork using the ClipGallery, and they came to understand SD-oriented issues as familiar occurrences in their daily lives.

The total number of photographs registered in the ClipGallery is 249. Examples are shown in Figure 2. A student took a photograph of ‘Recycle boxes’ as SD issue. She described a reason as ‘we can prevent to use new resource by recycling so that good environment will be kept. (Figure 3(1))’. Another students showed an ‘eco bag’ as SD oriented issue and explained ‘Eco bags are reusable. They reduce rubbish of plastic bags. This also reduce damage for environment.(Figure 3(2))’

Table 3 shows the association words and reasons expressed by ten or more students. Majority of the students, over 70%, are reminded of the term of ‘Recycle’. They also noted ‘Recycled paper’. This fact shows that the most represented words and images of SD among students is ‘Recycle’. Moreover, there are the terms of ‘My chopsticks’, an ‘Eco bag’ and ‘My tumbler’. These words mean that students are conscious of bringing their own chopsticks, bags and tumblers, instead of using the disposable items offered by the shops. Therefore, these terms may indicate a common consciousness in students that they need to reduce disposable item use. The idea of reducing disposable item use is reflected also in the word of ‘Ziploc®[1]’. In addition, students may understand the phenomenon relevant to power generation and energy savings as SD, because they find solar-power generation, wind-power generation, a solar panel, energy saving and an eco car as SD oriented terms. Bicycles and ‘EcoNavi[2]’ are also raised with the reason of energy saving. The word of ‘Organic’ is represented as health issue as well as environmental friendly.

The above issue points the notes that students tend to consider of taking environment-friendly action, such as to avoid disposable item use, recycle and energy saving, as SD. Some students chose photographs and described words of goods and product names. This issue means that the advertisement and promotion by private companies may be a factor to form students’ SD images. From this study, it may be suggested that activities of SD and ESD in Japan have mainly progressed in environmental aspects for students.

SD is a modern slogan in the promotion of science education. I would like to investigate students image of SD and to develop effective educational programme for ESD towards students.

CURRICULUM STANDARDS FOR TEACHING PHYSICS IN BRAZIL

Fernanda Ostermann[1] and Erika Regina Mozena[2] and Cláudio J. de H. Cavalcanti[3]
[1,2,3]Universidade Federal do Rio Grande do Sul - Brazil

Abstract: This work, as part of a PhD thesis, aims to investigate and monitor the whole process of development and implementation of curriculum standards for physics which has been made in the state of Rio Grande do Sul, Brazil. We have analyzed the development process (in which the authors of the present work have participated), the continuous teachers training process, and their implementation in the classroom, by investigating how teachers react to these changes and if something really changes in their physics teaching activities. All the research is enlightened by the Wertsch sociocultural perspective (Wertsch, 1993), which integrates Vygotsky and Bakhtin theories. We also take into account that the actions of these teachers are guided by their professional knowledge (Porlán et al., 1997 and 1998). We had used a qualitative approach, with participant observation, using as sources official documents, video recordings of training courses for teachers and classroom interventions, as well as semi-structured interviews. Preliminary results indicate that the problems in the organization of the development process have given rise to a material in which, among other inconsistencies, the interdisciplinarity have been barely addressed. Also, there was little autonomy given for teachers to implement the necessary changes because the training process was focused mainly on content topics, devoting much little space for discussions about important pedagogical issues which could guide the teachers to promote better classroom implementation of these curricular standards.

Keywords: physics curriculum, continuing education of teachers, educational policies, reports of experiences.

1. STRUCTURE AND PUBLIC POLICIES FOR EDUCATION IN BRAZIL

Brazil is going through a slow process of curriculum change which truly began in 1996 when was approved a law called “Guidelines and Bases for Education” (LDB), which establishes compulsory a primary education of eight years (increased to nine years in 2001) and secondary school of three years (see table 1). These guidelines also provide that the federal government, in collaboration with the several state and municipal governments, should establish ways to guide these curricula.

According to this law, the Curriculum Guidelines were approved in 1998 and establish that the high school level, the only level in which physics is taught, will be organized in three knowledge areas: 1 - Languages, Codes and its Technologies, 2 - Natural Sciences, Mathematics and its Technologies and 3 - Humanities and its Technologies. Moreover, these guidelines also stated that the main focus of the teaching process may be directed to the development of abilities and competences related to these areas, and not only to its content topics. Also, the importance of interdisciplinarity and context based learning are emphasized.

Age	Duration	Appropriate Designation	National Common Base
6 -14	9 years	Ensino Fundamental (primary education)	• Portuguese • Native language (indigenous and migrants) • Mathematics • Science • Geography • History • Foreign language • Art Education • Physical Education • Religious Education
15-17	3 years	Ensino Médio (secondary education)	• Languages, Codes and its Technologies • Natural Sciences, Mathematics and its Technologies • Humanities and its Technologies

Table 1 - Organization of primary and secondary education free and compulsory in Brazil

In 2000 and 2002 the Federal Government published the National Curriculum Parameters (PCNs) and, subsequently, the Curriculum Guidelines for High School Level in 2006. All these guidelines possess non-compulsory character. However, despite they establish and reinforce the teaching focused in abilities and competences (for political and structural reasons), they have not improved effectively the education in Brazil. One consequence in physics teaching is that the physics classrooms in high school level remain centered basically in simple formula application and resolution of exercises, as shown, for example, in the work of Ricardo (2005) and Ricardo & Zylbersztajn (2002).

Table 2 - Main resolutions in public policy for education in Brazil

In the State of Rio Grande do Sul (see figure 1), these national guidelines have not experienced much penetration and only in 2008 the local authorities developed the curriculum standards for this state, as an answer to the quite unsatisfactory performance of students in the state and national evaluation exams. This document was supported by the national guidelines

(PCNs and Curriculum Guidelines for High School Level) and was developed by a team of consultants, at least two per knowledge area.

Figure 1 - State of Rio Grande Sul highlighted in red on the Brazil's map.

This work reports this whole curriculum change process in the state of Rio Grande do Sul and investigates how teachers have reacted to these changes and if it really improves the physics classrooms, as expected.

2. PROPOSED CURRICULUM FOR PHYSICS EDUCATION OF RIO GRANDE DO SUL

Figure 2 - Curriculum guidelines Sciences, student and teacher's books.

The government actions at Rio Grande do Sul, for both primary and high school level, is directed to improve education by focusing the student learning on the development of abilities and competences, highlighting what we call basic transversal competences (reading, writing and solving problems) and, additionally, giving special attention to context based learning and interdisciplinarity. From this perspective, the main goal of the education process is shifted from the content topics to be learned to the development of skills (abilities and competences) articulated to these topics, since they need to be contextualized, articulated and applied to other areas of knowledge than physics (see figure 3).

Regarding the content of physics, the proposed curriculum does not bring new features compared to other official documents, but seeks to contextualize and illustrate his proposals, discussing in depth about the purpose of teaching physics and how to do it, pointing out appropriate strategies for this purpose. We chose to suggest a single sequence proposed in this paper, derived from official texts, which begins in the first year of high school, with the topic "Universe, Earth and Life."

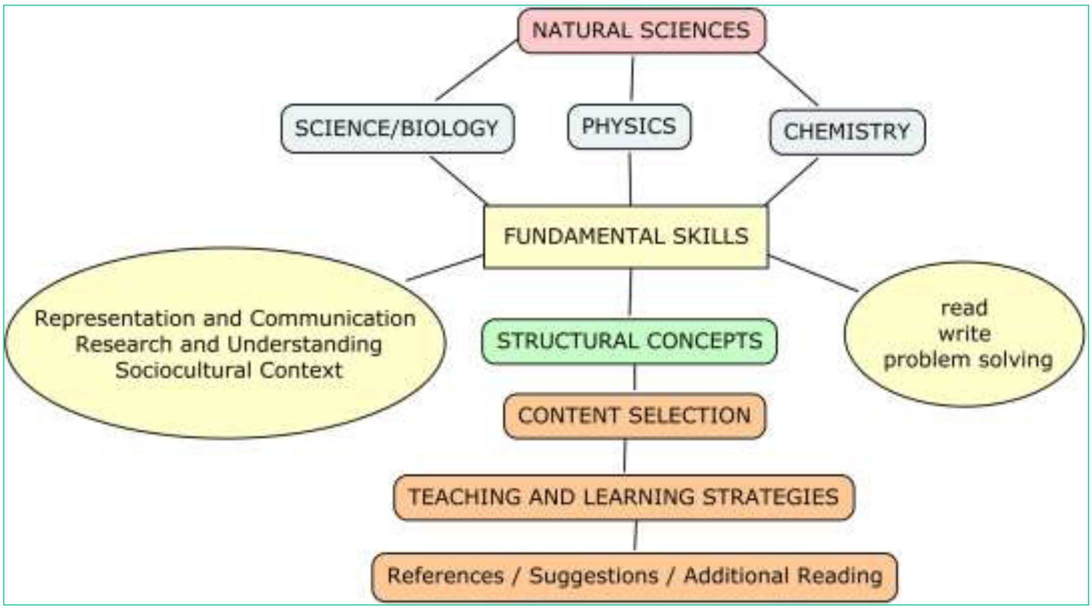

Figure 3 - Structure of the curriculum guidelines of Rio Grande do Sul.

This sequence was chosen because its potential to bring enthusiasm to students in their first contact with Physics. It has been thought to be developed under the structurating theme called "Universe, Earth and Life," which covers issues relating to the origin of the universe and our planet and all the Physics contents relevant to school. To assist the teacher in this process, since the textbooks do not deal with this approach, we have written a guide to the teachers showing how to start and advance the study and, additionally, providing a text with diversified activities on this topic, suggesting additional references.

Physics in secondary school	1º year	2º year	3º year
1st half	Universe, Earth and life	Sound, image and information	Electrical equipment and telecommunications
2nd half	Movements: changes and conservations	Heat, environment and energy uses	Matter and radiation

Table 3 - Suggested content distribution on the curriculum guidelines of Rio Grande do Sul

This topic can also help the approach of natural sciences in high school to establish in an interdisciplinary way, since all other topics in this area have close relationships with it. We believe that this could be a good alternative to start working interdisciplinarity with students and.

3. RATIONALE

The impact of these new educational policies is analyzed on a sociocultural framework (Wertsch, 1993), taking into account that the actions of these teachers are guided by their professional knowledge (Porlán et al., 1997, 1998). We adopt the curriculum perspective of Silva (2010), a renowned Brazilian specialist on curriculum theory.

These frameworks provide the elements needed to support the understanding of the psychological processes involved, the discourse and actions of some physics instructors throughout the process focused by this study.

4. METHODS

The research approach has involved the direct and prolonged contact between the researcher, the environment and the situation being investigated, usually through intensive field work. The qualitative research is known suitable in this case, because it aims to “capture the multidimensional nature of the phenomena in their natural expressions and capture the different meanings of lived experiences” (Rosa & Arnoldi, 2006, p.66).

Several sources had been used:

- Analysis of the development process of physics curricular standards and its possible implementations in the classroom;
- Video recording and collection of written material in the teachers training;
- Semi-structured interviews with teachers and the *multipliers* (professionals responsible for conducting the teachers training process) and governmental authorities.

Observations were conducted and the method chosen was the *participant observation* (Rosa & Arnoldi, 2006).

5. PRELIMINARY RESULTS, CONCLUSIONS AND IMPLICATIONS

Like any public policy in Brazil, the curriculum standards for Physics of the State of Rio Grande do Sul was slowly developed (2 years). Although the consultants' work has been done with much liberty, the weak interaction between the members of the consultant team has to be mentioned. A major result of this flaw is the lack of better integration between the texts of the standards of the *Natural Science* knowledge area (comprising physics, chemistry and biology), which goes against the pedagogical principles of these standards which stand the interdisciplinarity as a fundamental aspect in science education.

In the particular case of physics, it had been developed in some degree of agreement with other official documents, but it attempts to contextualize and illustrate their proposals, bringing to the teacher fruitful discussions on the purpose of teaching physics, pointing out appropriate strategies to achieve this intent. It suggests that teachers should begin the physics classes in an interdisciplinary and contextualized way, adopting the topic “The origin of the universe”, articulating their proposals with the ones of chemistry and biology teachers. However, this was frustrated by the way by which the standards of other areas (biology and chemistry) had been built. They departed from different themes and this interesting topic is not covered by the textbooks commonly used in Brazil.

The state government has offered courses for the teachers, addressing fundamentals of the new curriculum standards in the State of Rio Grande do Sul. These courses were performed by trained personnel, but the poor logistic organization undoubtedly brought many difficulties to the teachers understanding of the proposal. We also observed political problems in some cities in which we have followed the courses, disrupting the work that teachers should perform.

It is worth to mention the little autonomy left to the teachers to implement the main goals of these standards in their classroom activities. We have attributed this problem in part to the problematic conception of the training courses, mostly focused in content topics without exploring the suggested methodologies of teaching and learning physics. To perform an education project based on abilities and competences, in which the context based learning and interdisciplinarity plays an important role, it would be required to give total autonomy to the teacher. Besides, the teachers' knowledge on how to deal with context based learning and interdisciplinarity in their classes, was not well addressed. An example of this little autonomy can be seen in the final projects that teachers have developed along the course, which mostly turns the classes more fun and informative, reducing the interdisciplinary character to a simple choice of a common theme between different knowledge areas, without showing the strong relationships between them and how these relationships can constitute a whole new body of knowledge.

The future of these standards is uncertain, as the state undergone a great change in its political direction in last elections. Despite this, we will continue to investigate the future implementations of these standards in physics classrooms.

TEACHERS' VIEW ON A NEW SCIENCE SUBJECT: SCIENCE FOR THE CONTEMPORARY WORLD

Carolina Pipitone[1], *Digna Couso*[1] *and Neus Sanmartí*[1]
[1]Dept. Didàctica de la Matemàtica i les Ciències Experimentals. Universitat Autònoma de Barcelona, Spain

Abstract: This research analyzes the implementation of a new subject for the post-compulsory secondary school called "Science for the Contemporary World" (SCW). The main goal of this research is to identify the differences between the implemented curriculum as reported by teachers (IC), and the Potential Curriculum (PC) for this subject according to the official curriculum, science education literature and other theoretical sources. SCW demands from teachers a challenging new conceptualization of science and science teaching, within the competence-based and science for public understanding perspective

This paper presents the results obtained from a series of interviews to both innovative and standard teachers. Data analysis shows that there are different ways of interpreting the new subject among them, in particular regarding what, why and how to teach, signalling four different models or profiles for the subject.

Keywords: Science for the contemporary world, Science for Public Understanding, Curriculum, Competence-based Framework, teachers' perceptions

BACKGROUND, FRAMEWORK, AND PURPOSE

During 2006, the education law was modified in Spain with the approval of the Spanish Organic Law (LOE) which generated a new official curriculum that included a new subject for the post-compulsory secondary school: *science for the contemporary world* (SCW).

This subject has no precedent in post-compulsory education –post-16 years old-. Despite in this period the students have to choose between different areas (humanistic or scientific) with different subjects, SCW is compulsory to all of them. In this sense, it is a scientific subject for all at the post-compulsory level. Other characteristics of SCW are that it has 2 hs. class per week is a minor subject in terms of length and role in the external evaluation (it is not included in the external university entrance examination) and it can be taught by teachers with very different profiles (not only science teachers but also humanistic teachers such as philosophers) . Finally, one of the main characteristics of SCW is its open curriculum, which means that there are some general guidelines published at official level, but the subject is presented as not rigid and organized around five main themes to be studied at wish: Our place in the Universe, Health, Sustainability, New materials and Global information.

The main goal for the introduction of this new subject is reducing the deficit of scientific knowledge of citizens within a *science for all* and *STS* perspective. To do so, SCW follows the curricular trend of many countries inspired in the work of Fensham (2002), Hurd (1998), Jenkins (1999), Millers (2004) and Osborne (2002), among others.

This research aims to identify the vision and patterns of implementation of the subject according to teachers' perceptions of SCW and reports of their practice, to make explicit what we call the Implemented Curriculum (IC). The purpose is to compare the IC with the Potential

Curriculum (PC) of the subject, defined by the official curriculum and current research in science education.

Hence, the research questions we expect to answer are: What are the similarities and differences between the Potential Curriculum (PC) and the Implemented Curriculum (IC) of SCW, according to the teachers? What is the teachers' perception about SCW? Can the differences between the PC and the IC be related to teachers' science education expertise?

RATIONALE

We have characterized the PC based on both the official curriculum and the extensive literature on proposals for scientific education with a socio-cultural emphasis that inspire the theoretical rationale of this subject. Regarding the literature review, frameworks such as STS, Science for all, and projects such as Public Understanding of Science (1985) were reviewed. The characterization process let us identify three intended didactical goals for the new syllabus:

a) **Promote the development of competences to perform well in society**. This goal is not related to the concept acquisition of classical science subject-matter knowledge, but about how students learn to *mobilize* concepts, procedures and scientific attitudes, in order to solve a complex problem and make rational decisions. This research is based on the competence framework defined by the DeSeCo program (2001) and the official curriculum.

b) **Emphasize science as a product of culture.** The PC is referred to the vision of science which comes up from the intersection between science and the broader social context in which its products and processes are situated. They are typically part of public discourse, and require certain sets of skills and abilities from those engaged in reasoning and argumentation about them (Forbes & Davis, 2008). This justifies the need for a scientific literacy citizenship.

c) **Use relevant contexts to address the learning of contents**. In SCW it is expected that the selection of content is relevant to students. Also, it has to facilitate meaningful learning of scientific knowledge to be transferred to other contexts and situations. From the educational point of view, the approach would allow a balance between the teaching of science as preparation for science, and science education for citizenship (Gilbert, Bulte, & Pilot, 2011) .

In order to reach the previous goals, SCW has to be conceptualized and implemented by teachers properly. This involves that teachers' should develop a particular Didactical Content Knowledge for SCW, a concept analogous to the PCK framework that it is common in the Anglo-Saxon community. According to Henze et al (2007) characterization of PCK, this implies teachers' knowledge of 1) the instructional strategies concerning a specific topic (SCW), 2) students' understanding of this topic, 3) ways to assess students' understanding of this topic (all three relevant aspects of *how to teach*), and 4) goals and objectives for teaching the topic in the curriculum (*why to teach*). Within the perspective of didactical transposition for school science that we hold (Izquierdo & Adúriz-Bravo, 2003), it is necessary to add to Henze's definition of PCK and emphasis on a reflection and re-elaboration of the actual content or *what to teach?* In this sense, this work structures the analysis of the PC and the different patterns of the IC identified around the key dimensions: *How to teach? Why to teach?* and *What to teach?*

METHODS

For characterizing the IC an empirical study was made. During the first year the subject was implemented, five "innovative teachers" (IT) were selected and interviewed (T1, T2, T3, T4, T5). They were defined as innovative due to the fact that they held strong connections to science education research and were part of innovative teacher groups. During the second year of implementation another five interviews were done, this time to "standard teachers" (ST) who were known as not having links with research groups in science education (T6, T7, T8, T9, T10). All teachers in our sample had different scientific backgrounds and were interviewed the first year that they were in charge of the SCW subject.

The interviews were semi-structured, face-to-face and detailed with approximately 1h of duration. Teachers were asked to share their perceptions on the subject and to discuss the actual programmed and materials they were using to teach it.

From the analysis of teachers' answers we have developed 3 systemic networks for each key dimension (*what? why?* and *how to teach?*). For each network, main categories and several subcategories were identified at different levels, depending on teachers' PC understanding.

The categorization process of the interviews was carried out by analyzing the transcripts from all the interviews, the reflections teachers' send and other portfolio documents that were shared, according to the Constant Comparative Method (Huberman & Miles, 2002).

RESULTS

In this section we will show the most relevant results obtained for the three key studied dimensions: *What*? *Why*? and *How* to teach?

We start the comparison between teachers' viewpoint and the PC by analyzing their views on the first dimension, *why* to teach? (Table 1). For the sake of space, only one aspect is shown in depth. This is the category *Role of the subject in the students' curriculum,* which help us to identify how the teacher interprets the grounds on which the subject is based.

The more relevant result in this category is the difference between teachers' view on the goal of the subject. In our sample two extreme goals are identified, which are *Extending what we know about science* and *applying what we know about science.* Whereas the latter viewpoint, basically hold by innovative teachers (IT), is related to the idea of scientific competence and thus more coherent with the PC, the first standpoint (more specific of the ST group) is that of a subject complementary to the other science subjects the students have.

			Viewpoint coherent with PC	**Viewpoint dissonant with PC**
Why to teach?	Role of the subject in the students' curriculum	Extend what we know *about* science	**T1,T4, T5**,T8	
		Apply what we know about science	**T2,T3,T4,T5**	
		Extend what we know *of* science		T6,T9,T10
	Development of students'	Critical thinking about science and society	**T2,T3,T4**,T8	
		General culture: as Scientific culture	**T2**,T8,T7, **T5**,T9	
		General culture: as information		**T5**,T6,T9,T10
		More traditional science content		T6,T7,T10

Table 1- Why to teach?

In addition, the category *Development of students'*, identifies the objectives in relation to the knowledge that students must meet. The more relevant aspect in the general culture is the difference in the way in which teachers conceive this category, one of them according to the PC.

On the one hand we found general culture as scientific culture that is the students must have a certain mastery of scientific knowledge. This implies they can understand, and consequently apply, the scientific knowledge in different contexts and situations at the society. In the other hand, we have the category general culture as information, where the point of view is not consonant with the PC, teachers consider that it is only necessary that the students are within reach of the information and knowledge on the scientific leading edge.

This difference is important, because depending on how the teachers understand the concept of scientific culture, it will be reflected in their understanding and work in class.

Regarding the contents of the subject (*What* to teach?), the analysis shows that the aim of interdisciplinarity of the PC becomes a challenge to both IT and ST teachers, who both express a tendency towards teaching topics related with their scientific background. However, there are differences between these two teacher groups regarding to the selection of contents. While ST teachers refer mostly to topics within the subject textbook, IT teachers show more opened to contents related to current events. In addition IT expresses the importance of working with meta-disciplinar contents such as diversity of organisms or materials, remarking the need to work within the competence perspective of the PC.

One relevant aspect regarding what is taught is teachers' flexibility to change the sequence of contents. In general almost all teachers follow a standard curriculum model following the order proposed in the textbook or official curriculum. Also, they have shown some concern for complying with the syllabus, which is a characteristic of the traditional science subjects that have a closed syllabus which would be subject of an external examination, but shouldn't be the case in SCW where the curriculum is explicitly left open.

Regarding the dimension *How* to teach?, an interesting difference between both teacher groups is that of IT teachers facing the challenge of selecting and implementing new methods for a new subject, whereas ST teachers seem not to face this problem. In this sense, IT teachers introduce innovative classroom strategies and activities (discussions, role play, evaluation, etc.), despite stating that they have difficulties to manage them. ST teachers, on the contrary, do not state any methodological difficulties because their classes are based on traditional teaching methods and content. The most common difficulty for IT lays in the assessment of learning, in order to prove that the student can solve problems competently, i.e. how to evaluate the new activities. ST teachers consider that it is important that students learn scientific concepts, and hence, the tests are based on conceptual evaluations and show less difficulty for them.

Different ways of understanding SCW

From the analysis of the interviews and taking into account the three dimensions mentioned above, we have found different ways of understanding the subject, which we call models of the subject. These models may or may not be in complete agreement with the PC and can show coherence or incoherence between the portrayed vision of why, what and how to teach. These identified models are: *Epistemic model*, *Utilitarian model*, *Controversial model*, and *Academic inspired model*.

The *Epistemic model* is defined by a subject that let us know what science is and how it works. In this model the most important goal is to deepen the scientific knowledge of students, not only of science but about science. In this sense, the goal is on one hand to learn how scientific knowledge is generated (issues related to the nature of science), and on the other hand the Epistemic model also gives importance to the refining of conceptual models of the student.

The next example is of teacher T1, whose perceptions of SCW inspired this model.

> “[the goal of the subject is] on one hand to see **the great theories** that allow us to see the world. Some of the most important are: where do we come from? How do we work [...]? And on the other hand, **how science works**”

The *Utility model* defines a subject that help us in daily science related contexts. Is a subject in which the students apply the content learned in previous scientific and traditional subjects to everyday life situations, and so they are working on socio-scientific issues, in context and globally. Hence, the teaching and learning is devoted to the mastery of applying science to daily contexts and not the mastery of the content per se.

The next sentence of the teacher T4 showed an example of this model’s philosophy.

"We will do **things that are day-to-day,** and they are things which, even though in Greek philology graduates are perhaps of interest to you, because **maybe one day you'll have to decide** if you want assisted reproduction or not [...], and to decide that they must know something”

The *Controversial model* defines a subject that overall help us to recognize controversies and make decisions when ethical issues are involved. This model pays more attention to the controversial nature of most scientific issues of social importance today, and the need to be critical on them. The next example of teacher T3 describes this model:

> "[the objective of the subject is to] train future citizens to have a **critical view of science or current affairs** [...], learn to be critical, to have an opinion and know that all are valid, that all can be defended”

The *Academic model* defines a view of the subject as one devoted to learn more science, both reinforcing previous knowledge and learning about the new scientific advances. This model emphasizes the needed to learn more, updated scientific knowledge without the critical thinking standpoint. The next example shows a sentence of teacher T10, whose view inspired this model.

> "These students more often have done nothing of biology since eighth grade, no science at all. There are some issues that are difficult to understand [...], most of all the latest advances [...], **some concepts of biology should be reinforced,** and you have to explain them well”

Teachers’ perception of the subject according to these models and the dimensions that organize them is shown in Figure 1. The dotted lines refer to the teacher who inspired each model and holds a coherent view of it. In contrasts we found that most of the teachers interviewed show an hybrid perception of the subject, with aspects of different models being emphasized in their questionnaires Some interesting views are found, such as T7 is an antagonistic combination where *Epistemic model* in relation to why to teach and what to teach, and the *Academic model* in relation to why, what and how to teach?

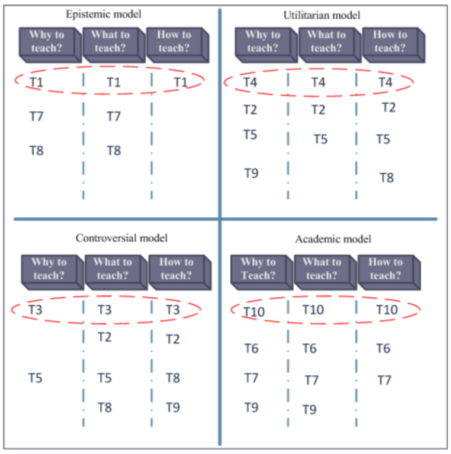

Fig. 1 Models of the subject

Despite its differences, results show that the *Epistemic model, Utilitarian model,* and the *Controversial model*, are all in agreement with the PC. In contrast, the *Academic mode* based on dogmatic traditional view of science and science content and teaching distorts the purpose of the subject and is therefore not consistent with the PC.

CONCLUSIONS AND IMPLICATIONS

Our first conclusion is related to the different ways of interpreting the subject shown by teachers and that different models of the subject coexist. However, some of them are more coherent between purpose, action and content with the PC than others. It is important to remark that there are similar conclusions in other works. That is, the nature of a discipline includes a teacher’s understanding of the history, philosophy, and sociology of the discipline. (Gess-Newsome, 2002). Therefore, the viewpoint of the SCW depends on the teacher's understanding about the nature of the discipline.

From this diversity of perceptions we have identified four models presented and which we can conclude that three of them (Epistemic, Utilitarian & Controversial model) are in agreement with the PC, where each highlights some of the objectives proposed by the PC, while there is a model (Academic model) that distorts completely the objectives of the PC (4/9 teachers). While there are different models, most of the teachers have hybrid viewpoints regarding the subject. In turn we have found that there is general consistency in the teachers' discourse between the dimensions: *why* and *what to teach*? On the other hand, the dimension of “*how to teach*?” can be more eclectic among models, showing the always difficult tension between both knowledge and purpose, and action.

Moreover, we have found that teachers with more didactical resources (mostly those of the IT) implement the subject SCW more coherently with PC than non-innovative teachers. However, this does not mean that being an IT teacher guarantees a coherent model for the subject neither a view close enough to the PC when implementing the subject.

Also we have found that teachers with more didactical resources (mostly those of the IT), are more concerned with their own domain of the knowledge to be taught This is due to the challenge of the subject they realize they have to face, and hence, a lack of knowledge about the content breeds insecurity for teachers to propose new activities (such as debates and role play) and particularly about how to evaluate them.

Finally, despite being an open syllabus, most teachers feel constrained regarding the selection and sequence of contents by structural factors, for example official themes, the textbook, time and lack of knowledge among others.

MARXISM IN SOCIOCULTURAL PERSPECTIVES AND IMPLICATIONS FOR SCIENCE EDUCATION

Flavia Rezende[1], *Paulo Lima Junior*[2] *and Fernanda Ostermann*[2]
[1] Universidade Federal do Rio de Janeiro (Brasil)
[2] Universidade Federal do Rio Grande do Sul (Brasil)

Abstract: Sociocultural approaches to science education originated in Vygotsky"s studies, which were developed under the influence of Marxism. In this paper, we attempt to point out how Vygotsky incorporated the main categories of dialectics in new concepts used to formulate his theory of historical-cultural development. These concepts, used lately as a theoretical framework for much of the sociocultural research and curriculum proposals in science education, are related to social interactions and to the role of language in learning and teaching. However, the Vygotskian project of reforming the psychology based on the Marxist perspective considering the broader institutional forces in human consciousness has not effectively been accomplished. Thus the construction of a sociocultural framework in which social and institutional levels, interpsychological and intrapsychological analysis can be integrated without being reduced to one another remains to be done. In order to contribute to this endeavor, we discuss some educational proposals that are based on dialectical materialism to relate teaching and learning to the concrete conditions of human existence and suggest implications for science education.

Keywords: dialectical materialism, sociocultural perspective, science education.

DEFINITION OF THE PROBLEM

Sociocultural approaches to science education originated in Vygotsky"s studies, which were developed under the influence of Marxism. In this paper we attempt to point out how Vygotsky incorporated the principles of dialectical materialism in psychological intermediate categories that he used to formulate his theory of historical-cultural development. These concepts, used lately as a theoretical framework for much of the sociocultural research and curriculum proposals in science education, are related to social interactions and to the role of language in learning and teaching. However, the Vygotskian project of reforming psychology based on a Marxist perspective considering the broader institutional forces in human consciousness has not effectively been accomplished. Thus, the construction of a sociocultural framework in which social and institutional levels, interpsychological and intrapsychological analyses are integrated without being reduced to one another remains to be done (Wertsch, 1985). In order to contribute to this endeavor, we discuss some educational proposals based on dialectical materialism to relate teaching and learning to the concrete conditions of human existence and suggest implications for science education.

MARXISM AND THE HISTORICAL-CULTURAL PSYCHOLOGY

The analysis presented in this section intends to argue that Vygotsky took hold of the main categories of dialectics (Engels, 1979; Marx and Engels, 2004) to build his cultural-historical theory of human development.In his major works, Vygotsky used the dialectical method to organize the review of the literature of his field producing a synthesis around two extreme and opposed positions such as thesis and antithesis: “all theories range from the identification or fusion of thought and speech, on the one hand, and his equally absolute disjunction and segregation, almost metaphysical, on the other” (2003a, p. 2).

The unit of analysis of any theory that adopts dialectics as the philosophical foundation must be complex, i.e., it must consist of parts and relations of tension between these parties. Thus the strong opposition to the atomistic analysis developed by Vygotsky is not arbitrary. From their commitment to the Marxist dialectics Vygotsky turned to the study of mental processes, "their interdependence and organization structure of consciousness as a whole" (Vygotsky, 2003a, p.1).

The researcher who follows dialectical principles tries to find tensions in the relationship between the parties of the object of study that produce movement, which results in focusing process and history. For Vygotsky, only an historical theory of inner speech can handle the problem of thought and language (2003a, p.190). The following goals are then, necessary: "an analysis of the process as opposed to an analysis of the object; an analysis that reveals the dynamic-causal relations as opposed to listing the external characteristics of a process, i.e., a non-descriptive and explanatory analysis" (2003b, p. 86).

The production of synthesis cannot be considered continuous, since what was there before is qualitatively different from what was produced then. In this sense we can say that the production of synthesis represents a revolution. The notion of mental development to Vygotsky includes the concept of revolution as it happens in terms of fundamental qualitative transformations (Wertsch, 1985).

The Marxist materialism is well recognized in the sentence "it is not consciousness that determines life, but life that determines consciousness" (Marx & Engels, 2004, p. 26). This principle is implicit when Vygotsky postulates that all functions in child development appear twice: first, in the social level and then at the individual level, first between people and then inside the child (Vygotsky, 2003a, p. 64).

MARXISM AND THE SOCIOCULTURAL PERSPECTIVE: AN AGENDA TO SCIENCE EDUCATION

The development of Vygotsky‟s theory taking into account the broader institutional forces in shaping human consciousness was left unfinished, having been limited to the interpsychological processes (Wertsch, 1985). Attempts to expand this framework have been proposed with different directions depending on the theoretical categories emphasized, the social relationships considered and sometimes requiring an interdisciplinary approach.

Leontiev‟s theory of activity (Leontiev, 1982) can be considered an approximation to Marxist assumptions in that it elaborates the implications of labor activity in psychological processes. This theory considers that the activity depends on the situational context in society and elects work as the prototypical form of human activity. This context guides the selection of actions, the operating composition of these actions and their functional significance. An important issue in this framework is how the assumptions implicit in a situational context determine the selection of actions and their operating composition.

Frigotto (1994) relies on the Marxist concept of polytechnic and on the Gramsci‟s idea of „work as an educational principle‟ to reflect on and propose directions to education. He argues that from the last decades of the twentieth century, the introduction of microelectronics in the work process and the correspondent more complex cognitive tasks would require the formation of a new type of worker. In this context, the school should change in order to produce the flexible, comprehensive and polytechnic employees, endowed with understanding of technical and scientific universal principles. The centrality of science in the production process would definitely justify the adoption of work as an educational principle.

Silva (1996) criticizes this proposal demanding more consistency with Marxist principles. In his view, the principle of unity between conception and execution or between intellectual and manual work would be a postulate to be followed in combining work and training and in the goal of training a „polytechnic" man. He maintains that molding education in accordance with changes in the skills required by new technologies used in production relates solely to the content, leaving out the social and political elements involved therein. Furthermore, the author criticizes the rationale that admits a close match between the demands placed by the world of work and the results provided by educational goals, which are central to human capital theory, much criticized by educators in the 80s.

The idea of broader institutional forces in shaping human consciousness has been emphasized recently by sociocultural approaches (e.g., Lemke, 2001), which strengthen the awareness that, in dealing with education, we are dealing with a social, cultural and institutional objects, which would involve the systematic analysis of research and education as institutions politically constituted and subject to the dominant ideologies in a certain time. Lemke (2005) criticizes the political implication of science education in the technical and scientific preparation of the work force and claims that science education has excluded many students by giving prominence to the acquisition of general and abstract principles and moved them away from everyday concerns. The predominance of an ideology that considers abstract learning nobler than practical learning has also contributed to strengthen the emphasis of science education on the acquisition of concepts and its distance from the issues related to social reality. The author advocates a reorientation of scientific education to social issues and problems that must be faced by all humanity in the twenty-first century, as the environmental crisis, social injustice and oppression and injustice to the young.

Analysing how science education is related to macrostructures such as neoliberalism Tobin (2010) concludes that scholars and policymakers have connected the production of knowledge through education to the production of economic capital. For the author, neoliberal social context, especially considering the increasing inequality and the creation of an economic elite oligarchy, has profound implications on science education. From a more critical position, he repudiates the idea that someone can accumulate capital even if it is science learning at the expense of a loss of another"s accumulation and asks how to produce equal learning gains not just equal opportunities to participate, as postulated by neoliberalism.

CONCLUSIONS AND IMPLICATIONS FOR SCIENCE EDUCATION

The criticism of Silva (1996) leads to the conclusion that science education should be reconsidered beyond the scope of changes that teaching and curriculum can provide to the extent that these changes in no way affect the separation between school and work and therefore, the social division of labor that underpins the capitalist model. In this view, recommendations on curricular reorientation in the sense that science education should address relevant issues to the students would not resolve social and educational inequalities. In a structural Marxist and relational perspective of connections between science education and work, the end of educational inequality is a political goal, not an educational goal. In this sense, educators and researchers in science education should encourage critical reflection on these relationships, noting that the conceptual tools of natural sciences are not sufficient, requiring interdisciplinary approaches that connect them to the social sciences. This reflection also cannot disregard the analysis of the broader relations between the production of science and technology and the process of capitalist production.

A CURRICULUM REFLECTION: NEW SCIENCE AND TECHNOLOGY CURRICULUM IN TURKEY

Meltem Savas[1], Ridvan Elmas[1] and Nilay Ozturk[1]
[1]Middle East Technical University, Turkey

Abstract: The goal of the present study was to investigate science teachers' perceptions and reflections over the new science and technology curriculum in Turkey. New science and technology curriculum was based on the constructivist principles, multiple assessment techniques, and many daily life activities. Semi structured interviews with 6 elementary science teachers from 6 different public schools were conducted in Ankara, Turkey. Interview schedule consists of 23 questions and it was organized in 9 themes. These themes are personal information, structure of change, acceptance of change, opinions about the change, feelings about the change, personal accountability for the change, implementation of the change, teacher competency in change, and effects of change on teachers. Additional data was collected through observation forms which include 2 subthemes. According to data analysis, teachers and students are attempting to adapt themselves for their new roles as a facilitator and an active learner. In this context the previous learning experiences of both are an obstacle for the adaptation process. In addition, crowded classrooms, individual differences, socioeconomic status, parents over valuing of grades, physical restrictions, and insufficient in-service teacher training were determined as the main problems of the implementation.

Keywords: Elementary Science and Technology Curriculum, Curriculum Evaluation, Curriculum, Elementary Science Teachers

BACKGROUND, FRAMEWORK and PURPOSE

In 2004, Turkish Ministry of National Education (MONE) began designing a new science and technology curriculum and disseminated new curriculum framework for implementation at the beginning of the 2005 fall semester. There were major changes in the paradigm, philosophy, teaching styles, teacher and student roles, unit organization, etc. The goal of the new science curriculum is to educate children as scientifically literate individuals regardless of their individual differences (MONE, 2004). The new curriculum is based on constructivist principles. There is an emphasis on conceptual learning, active learning and reflective thinking. Within the framework of spiral curriculum, main topics are repeated through the years. Finally, in the new curriculum, there are different assessment techniques such as performance assessment, concept maps, structured grid etc. Many significant changes was started to be implemented with the new curriculum and there are also some studies done as a preliminary results of the curriculum reform (Aydin & Cakiroglu, 2010; Ozturk, Elmas & Savas, 2011). However there is a need to design some other studies related to many aspects of the curriculum reform. Designing the new curriculum with modern educational ideas and paradigms in several cycles is the one side of the coin. The other side, teachers need time, training, activities to support their instructional design, new course books, sufficient subject matter knowledge and a paradigm shift in their pedagogies, and belief and value systems. Because there is mostly a gap between what was written on the curriculum and what was implemented in the classroom (Shkedi, 1998).

The purpose of this study is to determine the early evaluation of elementary science teachers' opinions and perceptions related to the new elementary science and technology curriculum and their transfer of the new reform ideas into their classroom practice.

RATIONALE

Teachers and students are producing their own curriculum realities in the classroom rather than following curriculum prescriptions. So, key actors in the design are the elementary science teachers since their awareness about the curriculum is crucial (Roehrig, Kruse, & Kern, 2007). To make permanent impact on the educational system, early evaluations of the new curriculum are of critical importance, in the direction of determining weak and strong points. The curriculum should be improved and redesigned at the unsatisfactory points continually.

RESEARCH QUESTIONS

1. How do public elementary school science teachers perceive the new curriculum?
2. How do public elementary school science teachers transfer curriculum changes to their classrooms?
3. What are the elementary science teachers' concerns about implementing the new curriculum?

METHOD

This is a phenomological study (Marshall & Rossman, 2006), which mainly focused on capturing the meaning of lived experiences of elementary science teachers' about the implementation of the new curriculum. In this research, a two-step sampling process was used while selecting the participants; a typical case and maximum variation sampling. Six schools which are chosen for the study are representative of average public schools in Turkey. In the second step, 6 elementary science teachers were selected from these schools. Any common experiences of elementary science teachers that emerge from great variation of years of experience are of special interest and valuable in capturing the core patterns, shared beliefs and different point of views.

A semi structured interview schedule lists the questions for the sake of ensuring the same style of query is pursued with each interviewee (Patton, 2002). All the interviews were tape recorded with the consent of teachers and were transcribed verbatim. Interview Schedule consists of 23 questions and it was organized in 9 themes. These themes are personal information, structure of change, acceptance of change, opinions about the change, feelings about the change, personal accountability for the change, implementation of the change, teacher competency in change, and effects of change on teachers. Additional data was collected with observation forms which includes 2 subthemes. These subthemes are the portrayal of the school and description of the classroom. Portrayal of the school theme consisted of 11 questions and description of the school theme consisted of 5 questions.

In addition, inductive content analyses were applied to analyze the transcriptions of interviews and observations. To be confident about the codes and themes, 3 researchers in the study coded all six interviews and observations by themselves and series of meetings were arranged to ensure inter coder reliability (96%) and the objectivity of the study. In this study, we assured credibility of the data by using method and analyst triangulation. We gathered data from interviews, observations and from documents (new curriculum program book) to achieve source triangulation. We ensured the analyst triangulation with working as a team of researchers (three) in the analysis processes. Peer debriefings involved formal and informal discussions with other researchers for finding alternative explanations and checking the emerging themes and design (Miles & Huberman, 1994). In order to establish transferability, thick and detailed descriptions of the characteristics of the setting, sample, and the processes were provided.

RESULTS

Structure of change

The change in the curriculum was vital in this reform; however, teachers' beliefs about these changes have an important role in their practice (Anderson, White and Sullivan, 2005). Therefore, teachers were asked questions about the nature of the change to reveal their beliefs. According to teachers the change in rationale is the most important change in the curriculum. Teachers emphasized the student-centered instruction as one of the most important thing bringing with the new curriculum. Teachers are not source of knowledge anymore; instead students construct their own knowledge. About this issue, teacher II stated that,

> "The rationale of the curriculum has been changed totally. Now, students interpret the knowledge and obtain the knowledge by themselves."

Both teachers and students are active and creative in the curriculum. Moreover, teachers are just facilitating the classroom instruction while students are independent learners. Another important change mostly stated by teachers was the activity oriented nature of the curriculum. However, teachers interpret the activities in different ways. Teacher II did not mention any difference in learning activities. Teacher II stated that,

> "Some of the experiments in the previous curriculum were named as activity in the current one. They are now performed both in and out of the laboratories."

Other teachers mentioned about the change in both the quantity and the nature of the activities. Some teachers mentioned the ease of performing them without any time or material problem although some of them listed the material finding as an obstacle in implementing the new curriculum. Besides, teacher III considered the games and activities as incentives for convincing students to learn.

While all the teachers pointed out the shift from the assessment of rote learning with open-ended and multiple-choice questions to multifaceted assessment with different tools such as rubrics, concept maps, performance assessment and structured grid; teacher II, and teacher III complained about the assessment of project based assignments. Teacher III expressed her complaints with the following words,

> "I think project based assignments are normally effective but they turned out to be a responsibility for parents rather than students. Students and parents focus on high grades and if students get low grades, parents feel unpleasant about the outcome and come to school to criticize me about the low grades. Therefore, project based assignments become an issue concerning the families now. Project based assignments are an issue when parents have to spend time and money."

All the teachers think that textbooks are simplified in terms of content, and they are full of activities and questions. However, teacher II criticized the textbooks in terms of figures and content load and gave the meiosis figure as an example that causes confusion in students' mind. Most of the teachers stated that they prefer not to use the traditional methods by making students more active in learning the process. Teacher IV and teacher V issued that their teaching style did not changed so, since they have already using student centered learning activities. These teachers are both the youngest teachers and the teachers who are enrolled in a graduate program. On the contrary, teacher III, who has the most teaching experience, stated that he could not change his teaching style due to his previous experiences.

Acceptance of change

In order to decide the teachers' acceptance of change we investigated their use of program book. We asked how frequent and for what purposes they use program book. When we analyzed their answers, we realized that the answers of teachers, interestingly, have a relationship with the teaching experience of the teachers.

Teachers with least experience (5 and 6 years of experience) do not prefer to use program book regularly while teachers with the most experience (23 and 31 years of experience) use it to follow the objectives and topics to be taught and the teachers with medium experience (11 and 17 years of experience) follow the program book when planning their lessons. Most of the teachers found the new curriculum understandable but have doubts about its usability in Turkish context.

Opinions about the change

The general opinions of the teachers about the change can be summarized as in Table 1.

Table 1. "General Opinions of Teachers about the Change"

	Teacher I	Teacher II	Teacher III	TeacherIV	Teacher V	Teacher VI
Content load	Sufficient	Sufficient	sufficient in 6th and 7th grade	sufficient in 6th and 7th grade, more intense in 8th grade	Intense	Intense
Spiral curriculum	Admire	Discontinuities	Need more time for repetitions	Admire	Admire	Admire
Daily life connection	Admire	Admire	Admire	Admire	Admire	Admire

Teachers are generally pleasant with the change in content load which is far less than the previous curriculum. However, when implementing the new pedagogies and ideas, teacher V and teacher VI have some problems in covering all the objectives due to intense content load. Moreover, teachers have positive opinions about the spiral nature of curriculum organization except the ones who complain about the difficulty and discontinuity between the repetitions of the topics throughout the years. Daily life examples in the textbooks are relevant both for teachers and students.

Feelings about change

Teachers feel happy about implementing the new pedagogies in their classrooms. Moreover, teachers feel sufficient in implementing the new curriculum especially when they get positive feedback from students. However, teacher II reported that he feels unsatisfied with the curriculum. The following sentence includes her reason for this;

> "I feel unsatisfied in my new role in the curriculum. I feel as if I am supposed to teach them more and more."

Almost all of the teachers have positive feeling about implementing the new curriculum. Their new role in the curriculum or using new pedagogies and paradigms did not cause much discomfort on them.

Personal accountability for the change

Teachers were asked about trainings they got about the new curriculum as an indicator of personal accountability for the change. Moreover, they were asked about what are the teacher responsibilities in the curriculum to determine how much they perceive themselves responsible.

Teachers generally complained about the lack and insufficiency of the teacher training organized by the ministry of education. Only teacher V did not complain about this deficiency. Because he worked in the school in which the new curriculum was piloted before dissemination. They learned the new curriculum by reading or participating to other training courses. Teachers consider participating training courses, willingness, acceptance, mastery in the content and model, preparing activities, open-mindedness, recognizing class as important responsibilities in implementation of the curriculum.

Implementation of the change

All the opinions and feelings of the teachers mentioned above affect their implementation of the new curriculum because the beliefs and knowledge of the teachers about the curriculum mediates the adaptation to the reform (Gess-Newsome, Southerland, Johnston and Woodbury, 2003; Pajares, 1992). Therefore, we asked them to learn about how they implemented and what kind of difficulties they encountered in implementation along with their opinions and feelings about the curriculum change.

When planning their first lessons with the new curriculum, teachers tried to find different activities, games and materials from web or books. In this phase, none of them got assistance from their colleagues, but they used the documents of Ministry of National Education (MONE), web and got help from some academicians. When teachers were asked the factors affecting their implementation of the new curriculum, all of them complained about the families. They stated that parents are unaware of the new curriculum and they suffer from the tasks their children are given. Each teacher mentioned the neutrality of the school administration, but some of them mention they need to be reinforced and be provided trainings.

Teacher competency in change

All teachers feel sufficient themselves in content knowledge except teacher one who feels insufficient in pedagogical content knowledge and content knowledge. Teacher II defended his insufficiency as;

> “I feel myself insufficient in subject matter knowledge because the science content is very broad. I am insufficient in biology, especially in meiosis, chromosome number change. I feel myself insufficient in science also because of tentative nature of science and technology.”

Teacher II and teacher V feel themselves insufficient in activity preparation either because of time restriction or lack of knowledge on how to do some experiments and activities. Teacher IV is the one who thinks that student-centered education is applied in her classroom. She described her classroom environment a bit noisy but warm and kind. Other teachers blamed physical settings, students’ insufficient background, mainstreaming students, crowded and unmotivated classrooms, diversity in discussion skills of the students, noise and seating arrangements for failing the implementation of student-centered education.

Effects of change on teacher

Curriculum change has caused some changes on all teachers to some extent. Some of them said that they changed drastically in terms of their perspectives, teaching styles, research habits. Others said they had chance to have new and interesting experiences whereas. Only teacher III mentioned no change with curriculum change.

> “There is no change at all. The only thing changing is the tools we use, not anything else. The blackboards became whiteboards.”

This quotation shows the beliefs of the teacher about the change in curriculum. Teachers' beliefs rather than their knowledge have effect on their decisions in curriculum implementation (Pajares, 1992). It is clear from the previous sections that the routines or practices did not change so after the curriculum reform. There is not a change in this teacher's decisions in implementing the new curriculum because of his core beliefs.

After presenting the results theme by theme with quotations, positive and negative viewpoints of the teachers about the new curriculum can be summarized as in the table below.

Table 2. “Viewpoints of Teachers about the Curriculum Change”

Positive Viewpoints	Negative Viewpoints
1. Decrease in the content load is the most important change. 2. Teacher is active and creative but the instruction is student-centered, the new role of the teacher is facilitator instead of instructor. 3. Students are more active and independent in the new curriculum. 4. New curriculum is more activity-oriented; lessons are designed as promoting knowledge construction of students. 5. The current curriculum requires the use of different assessment techniques such as performance tasks, project assignments, presentations. 6. Textbooks are simplified in terms of content load and they are more attractive for students. 7. Teachers are more proponent of the use of new pedagogies to make students more involved in learning process. 8. Teachers pointed out the usefulness of the spiral structure of the content organization.	1. According to teachers project based assignments became an issue concerning family, especially when parents are obliged to spend time and money to these assignments. 2. Although many teachers have positive opinions about the spiral curriculum, some teachers complained about the difficulty of and discontinuity between the repetitions of the topics throughout the years. 3. Teachers feel insufficient in activity preparation. 4. Implementation of the student-centered instruction is challenging because of physical setting, individual differences and classroom management problems. 5. New paradigms could not be internalized by parents, students and teachers in such a limited time span. 6. The workload of teachers is intense in the new curriculum. 7. Teachers demanded more support and encouragement from the administrators in the curriculum implementation process.

Observation forms

The schools, in which teachers work, were also observed in order to get an idea about the portrayal of the school and to describe the classroom. Schools were chosen from different district, but they were all in similar environments. All of the students have garden that ensure place for out of class activities. The schools also have computer laboratories, although some of the schools do not have science laboratories. There are about 1 to 4 science and technology teachers in the schools. Therefore, most of teachers have chance to collaborate with the teachers from their field.

In the classrooms whiteboards are used. There are also projectors in some classrooms. The classroom sizes are average and the seating arrangement is classical and the classroom sizes are not convenient for changing the seating arrangement flexibly. As teachers stated the classrooms are not suitable for student-centered instruction. They were designed more for lectures which is teacher-centered.

CONCLUSION and IMPLICATIONS

A major problem in Turkey is that curriculum reforms are espoused with overly big innovation ideas within unrealistically short timelines and with very limited economic investment in human resources (especially teachers) and supportive materials. In addition, there is a lack of organization and coherence between system components. In the design phase, involvement of all stakeholders of the system often neglected and the whole curriculum was designed with a small group of stakeholders. These deficiencies foster the retention of old methods and practices despite the new curriculum implementation efforts.

BECOMING A SCIENTIST MEANS BECOMING A CITIZEN

Dorothy V. Smith[1]
[1]Faculty of Education, La Trobe University
Melbourne, Australia

Abstract: Science education in every democratically governed society faces the same dilemma: that of catering in the same classroom for the intending science specialist and the future citizen (lay-person). This paper is concerned with the science education of the intending scientist.

The idea that science education in the compulsory years of schooling should be accessible to all students has driven science education in the developed world since at least the 1980s. In the focus on an appropriate science education for a citizen, the education of scientists has gone largely unexamined; however, the majority of science curricula developed for all students bear a remarkable similarity, across the years and across societies, to those developed in the immediate post-war period for the education of intending scientists.

I argue that today's social climate requires a new vision for the science literacy and the social understanding of the next generation of expert scientists. This is an approach that explicitly re-frames the intending scientist as both a scientist and a citizen. If we adopt this view it becomes clear that STS/Science for All curricula, once regarded as solely for the layperson, are indeed appropriate for all citizens. I illustrate the argument by considering aspects of the account of science given in Australia's new, first, national curriculum.

Keywords: science curriculum, secondary school, science literacy, science for citizens, science curriculum in Australia.

INTRODUCTION: THE PROBLEM

Science education in every democratically governed society faces the same key dilemma: how does one cater in the same classroom for the intending science specialist and the future citizen (layperson). This paper is concerned with the science education of the intending scientist. I argue that today's social climate requires a new vision for the science literacy and the social understanding of the next generation of expert scientists. This is an approach that explicitly re-frames the intending scientist as both a scientist and a citizen

The argument I present below comprises two key strands. The first is a brief account of recent trends within science education; the second is an account of a socio-political perspective that calls for a post-patrimonial approach to the education of intending scientists.

CONTEXT AND THEORETICAL POSITION

The underpinning theoretical position for this paper is that curriculum "functions to initiate pupils into the cultural, economic and political life of their society" (Carr, 1993, p. 1); the study of curriculum should help us to see how it "operates to transmit, sustain and contest the ideologies and social structures of society" (ibid). I deal here with the words written in curriculum documents rather than an enacted curriculum because my concern here is with formal policy intent as it is expressed through such documents. As Carr reminds us, "political questions about how society ought to be changed and improved always give focus and direction to curriculum questions about what should be taught and learned" (Carr, 1993, p. 1).

To some extent the position I adopt here derives from my location in Victoria, Australia. Australia has a federal system of government in which power is divided between states and Commonwealth Government. The states retain control over key areas, including police, hospitals, public transport and school education. Each Australian state has developed its own education system that differs from the others in a variety of ways: students begin school at different ages, school holiday dates do not coincide, and each state has its own school curriculum.

Although the Commonwealth Government nominally has no authority over school education, it has gained influence through providing funding, a process that began in the 1950s and 60s with Commonwealth grants to finance modern science laboratories in secondary schools. The Commonwealth Government has negotiated an agreement with the various states and relevant territories of Australia to develop a national curriculum, called The Australian Curriculum. When implemented, this will be Australian's first national curriculum. Science remains a key area of interest for Commonwealth Ministers of Education, and Science was one of the first subjects for which the Australian Curriculum was written. The policy context and politics of its development are outside the scope of this article.

TRENDS IN SCIENCE EDUCATION

The period after World War II saw substantial investment in science education. Several significant science curriculum projects were developed in the 1960s and early 1970s, largely aimed at senior secondary school science students: PSSC Physics (Physical Science Study Committee, 1960) was the first such project. The authors of these projects hoped to tempt the best students study science: the courses they produced were, largely, a preparation for further study in science. To some extent this was a continuation of the historical role that science has had in formal schooling.

The 1970s brought substantially increased student retention into the senior years of secondary school (Fensham, 1992): the idea that science education in the compulsory years of schooling should be accessible to all students, not just those who would continue to study science, has driven science education in the developed world since at least the 1980s. The focus has been on what might constitute an appropriate science education for a citizen. The consequent innovations in science curriculum can be thought of, broadly, as deriving from three emblematic international movements in science education: Science Technology and Society (STS), Science for All and scientific literacy. The most current of these ideas is that of scientific literacy or science literacy (Roberts, 2007). However, internationally, there was some disagreement as to whether a broad, socially relevant science education should be made available as the only offering or in parallel with the existing narrower formal system. This second formulation would see intending scientists continue with their preparation for further study while the 'layperson' would take 'Science for All' courses.

In Australia, almost from its inception, the Science for All movement saw the needs of the 'layperson' as different from those of the intending scientist (Fensham, 1985). Intending scientists were largely seen as a separate group and effectively exempted from the sort of science education deemed necessary for the future citizen. Further, because the science courses designed for intending scientists could be seen solely as a preparation for further study in science, these courses tended to teach a traditional and de-contextualized version of science. At the same time, views of inclusivity and access meant that it was also commonly held that every child should be allowed the chance to proceed to future studies in science. Thus, because Science for All/STS was not seen as appropriate preparation for intending scientists, any student who thought they might want to continue with science took the courses intended for future scientists.

Today, the accrued effect is that in many societies, including Australia, our vision for the scientifically literate citizen has become restricted to that of a participant in a scientifically literate workforce, and our vision for that workforce is largely framed by the traditionally perceived needs of academic scientists. Roberts (2007) describes this as Vision I for scientific literacy: a vision that looks to the canonical science of the academy for an account of what should be taught in schools.

I argue here that we require a fresh approach that explicitly re-frames the intending scientist as both a scientist and a citizen. If we adopt this view it becomes clear that the STS/Science for All curricula - once regarded as solely for the layperson - are indeed appropriate for all citizens. I give one example to illustrate this approach and then consider the extent to which the approach is supported by Australia's new, first, national curriculum in science.

A POST-PATRIMONIAL APPROACH TO EDUCATING FUTURE SCIENTISTS

Throughout the developed world, the social climate today requires a new vision for the next generation of expert scientists. I offer two warrants for this claim: the first is that science is a complex socially embedded institution which both shapes and is shaped by the societies in which it is practised (Aikenhead, 1994, 2006; Berger & Luckman, 1967; Chalmers, 1990; Charlesworth, Farrall, Stokes, & Turnbull, 1989; Kuhn, 1970; Latour & Woolgar, 1979); the second utilizes a social perspective put forward by the political theorist Anna Yeatman (Yeatman, 1997, 1998, 2000). I present a brief summary of this perspective below: more detailed accounts of this argument can be found elsewhere (Smith, 2006, 2011b; Smith & Gunstone, 2009).

The most significant social trend in the developed world over recent years has been the trend towards marketization. This trend has been accompanied by a substantial alteration in the relationships between citizens - now framed as consumers - and society in the broad. Critiques of science curriculum in schools frequently call for an updating of content and methods to reflect the substantial technological shifts that have taken place since the 1970s, and such updating is certainly needed. However, we should also examine the impacts of the shift to neo-liberal market driven priorities on the relationship between scientists and society. Studies of the public engagement with science document a gap between the needs of the community in the broad and the support that science is able to provide (Feinstein, 2011; Layton, Jenkins, Macgill, & Davey, 1993; Roth & Lee, 2002). Perhaps the best description of this gap comes in the choice of Layton and his colleagues to title their study 'inarticulate science'.

The word 'articulate' has two meanings. In its oldest sense it means to express oneself fluently or to speak clearly. Its other sense is to be jointed. The Layton report has been frequently cited in its first sense: "the formal language of science needs to be translated if it is to be accessible to ordinary citizens" (Fensham, 2002, p. 17). However, the way that Layton and his co-researchers use the word suggests that they intend it to have both senses: "there is a lack of articulation between the scientific notion of energy … and the understandings which elderly people invoke …" (Layton et al., 1993, p. 74). This is a richer usage than merely to speak clearly: one may speak very clearly but still not address the needs of one's audience. To call for articulation in the other sense is to directly address a need for flexibility on the part of science as it makes connection with 'the laity'.

Such flexibility is essential today because science professionals - indeed, all professionals - are faced with a need to establish with the laity a different relationship from the one that has sufficed until now. In the immediate postwar period governance was modeled along patrimonial lines, experts knew what was best and the laity followed their advice. Today we live in a neo-liberal, post-patrimonial climate: the dominant forms of governance in the developed world today give primacy to the rights and needs of each individual, and see social order as being brought about by the processes of a market (Apple, 2006; Ball, 2006; Marginson, 1986, 1997). Today, "[t]he older patrimonial economy where the householder owes protection to his dependents has gone" (Yeatman, 2000, p. 184): it is no longer appropriate that an expert assume the authority to speak for the layperson and instead the layperson expects to have a voice and be allowed to choose for themselves.

The usual response to today's altered circumstances is to ask that the ordinary citizen gain a substantial expertise in science, so that he or she might make responsible choices. Generally the science that is recommended is the canonical science of the academy. However, there is another response to the demand for a post-patrimonial relationship between experts and the laity: to see the role of the expert as supporting and enhancing the voice and choice of the ordinary citizen. I argue that this second approach is essential for the wellbeing of both the institutions of science and society in the broad (Smith, 2006).

If scientists are to operate successfully in a post-patrimonial society, they must have a grasp of the social context of science and better articulate their work within this social context. Scientific literacy should be seen as a process of a community rather than an attribute of an individual (Roth & Lee, 2002) more akin to Roberts' (2007) Vision II. Further, the place to first adopt such an altered view is in school classrooms: it is here that an insistence that the laity needs a sound grounding in canonical science has proved a block to a Science for All curriculum. Curricula such as 21st Century Science (Millar, 2000, 2006) are a significant movement in this direction.

WHAT MIGHT SUCH AN APPROACH LOOK LIKE IN PRACTICE?

Curriculum provides guidance about what should be taught in three key ways: it specifies what should be taught, what account should be given of the content, and to what end. If we keep in sight the view that an intending scientist is also a citizen, then perhaps the easiest and yet the most powerful first step is to attend to the account that we give of the science we teach. Corrigan and Fensham (2002) tell of the ways in which the canonical chemistry of acids and bases is transformed by the different accounts given by teachers in three different vocational education settings: nursing, lithography and winemaking. I offer an example here taken from my own practice as a schoolteacher at an academically oriented school before examining the account of science given in the Australian Curriculum.

Teaching Variation and Natural Selection

There are at least three ways that I can see to teach the ideas of variation and natural selection. The first involves a study of the fossil record, the second is to explicitly contrast the scientific account of evolution with creation stories from various cultures and religions, while the third is to teach about the development of antibiotic resistance in bacteria. All of these approaches involve teaching roughly the same science content knowledge: the first and the third also allow a range of experiments. In my time as a science teacher I have worked with my colleagues to try all three approaches, and have come to the view that the first approach is useful in Primary school and up to Year 8. The second approach allows for interesting debate, but it does show science in conflict with society in a way that can be unproductive for learning science. The third approach, on the other hand, is a powerful way to teach these ideas in Years 9 and 10 because it deals with an issue of immediate relevance to all students; of the three approaches described here, the third allows perhaps the most complex account of science and its processes, and it also gives students an area in which they can choose how to act. Not every student will grasp all the details of how bacteria develop antibiotic resistance – the science here is complex enough to challenge the most able students – but every student does come to understand that how he or she deals with antibiotics is important and has consequences for all of society.

As teachers, my colleagues and I were able to make a choice of how to approach teaching these ideas because the curriculum framework that we had at that time gave us these choices. However, whether Australian teachers will continue to be allowed such flexibility is not clear (Smith, 2011a, 2011b). Below I consider whether the Australian Curriculum for Science allows or facilitates different accounts of science congruent with the post-patrimonial approach that I have outlined in this article.

THE AUSTRALIAN CURRICULUM FOR SCIENCE

Science in the Australian Curriculum (Australian Curriculum Assessment and Reporting Authority, 2011) is organised in three strands: Science Understanding (SU), Science as a Human Endeavour (SHE) and Science Inquiry Skills (SIS). Science Understanding has four familiar sub-strands: Biological sciences, Chemical sciences, Earth and space sciences and Physical sciences; Science Inquiry Skills comprises five sub-strands that have to do with developing hypotheses, designing experiments, collecting and analysing data and evaluating and communicating the outcomes; Science as a Human Endeavour comprises two sub-strands: Nature and development of science and the Use and influence of science.

> In the practice of science, the three strands of Science Understanding, Science as a Human Endeavour and Science Inquiry Skills are closely integrated; the work of scientists reflects the nature and development of science, is built around scientific inquiry and seeks to respond to and influence society's needs. Students' experiences of school science should mirror and connect to this multifaceted view of science.
>
> To achieve this, the three strands of the Australian Curriculum: Science should be taught in an integrated way. (Australian Curriculum Assessment and Reporting Authority, 2011)

It seems reasonable to expect, then, that teachers will be supported in giving an account of science as a social institution. However, there are some other aspects of the curriculum that will undercut this possibility. The curriculum is developed around six overarching ideas that "support the coherence and developmental sequence of science knowledge within and across year levels". These ideas are framed to support the Science Understanding and Science Inquiry Skills strands, and they "contribute the development of students appreciation of the nature of science". There is no suggestion that they might support students' development of understanding of the use and influence of science in society: in other words, the overarching ideas are likely to support a canonical account of science. At each year level the various strands and sub-strands are elaborated into Content Descriptions and Achievement Standards. What is noticeable here is that there is substantial content and that, while it might be possible to adopt a variety of approaches, only one such approach is well supported by the materials provided within the curriculum.

This curriculum will form the basis of national testing in science: whether the tests will allow for a variety of approaches is not yet clear. One indicator of whether variety will be supported is what the curriculum has to say about diversity. The Australian Curriculum asserts that it "has been developed to ensure that curriculum content and achievement standards establish high expectations for all students. Every student is entitled to enriching learning experiences across all areas of the curriculum. Students in Australian classrooms have multiple, diverse and changing needs that are shaped by individual learning histories and abilities as well as cultural language backgrounds and socio-economic factors". However, only two groups are explicitly considered in detail: students with special education needs and students for whom English is an additional language or dialect. It is disappointing that the authors of this curriculum acknowledge the multiple, diverse and changing populations of Australia yet do not make a more explicit provision to support a diversity of approaches. They leave canonical science as the clear supported option.

CONCLUSION

A curriculum for the intending future scientist should present Science as the work of people with the full range of human faults, passions and perspectives, working as communities. All aspects of Science should be seen as socially embedded, inextricably linked with the communities in which Science developed and in which it is now practiced. A science curriculum should facilitate the development of articulate scientists: communication in appropriate and easily accessible terms should be seen as the normal work of science professionals and the science content should be taught in a relevant, appropriate and engaging social context. The new Australian Curriculum for Science might allow these things to happen, but it does not give a strong indication of supporting them.

TRANSFER OF A TEACHING-LEARNING SEQUENCE FROM GREEK TO ITALIAN SCHOOL: DO SIMILARITIES IN EDUCATIONAL SYSTEMS REALLY HELP?

Testa[1]*, A. Molohidis*[2,3] *S.Lombardi*[1]*, D.Psillos*[2]*, G.Monroy*[1]*, E. Hatzikraniotis*[4]

Abstract: The specific purpose of this paper is to investigate the changes that occurred in the process of the transfer of a Teaching-Learning Sequence (TLS) from the designer's to a host's context. Besides we discuss if the similarities between educational systems may actually favour such a transfer. The specific case concerns the transfer of a TLS on thermal properties of materials from the Greek educational context into Italian one. The research has been framed in the "*Adaptation* and *Re-Invention"* (ARI) theoretical model. According to this model, some "core" elements of the original TLS, namely, scientific concepts addressed, pedagogical approach adopted, ICT-enhanced aspects and the activities' sequence, have been first identified and then adapted for the new context. The resulting new core elements of the transferred TLS have been compared with those of the original TLS to investigate about the feasibility of the transfer. Results show that the similarities between the two educational contexts acted mainly as facilitators of the transfer process. Moreover, direct communication and interactions between the involved groups and an external expert helped significantly the process. Data from implementations in the two educational contexts show also similar positive effects on students' learning outcomes.

Keywords: Teaching-Learning Sequences; Knowledge transfer; Heat conduction

BACKGROUND, FRAMEWORK AND PURPOSE

Exchanges of successful educational practices and artefacts have become one important issue for debate within European Union. Despite the interest and profound educational and political implications, research studies devoted to document and reflect upon efforts to disseminate successful practices amongst different countries are rather scarce at least in Science Education. In this paper we address this issue in terms of a case study involving the transfer of a Teaching-Learning Sequence (TLS) (Meheut & Psillos, 2004) about heat conduction, originally designed by a group of researchers and experienced teachers located in the Department of Primary Education Aristotle University of Thessaloniki for compulsory lower Secondary Schools, Gymnasium (13-15 yrs students), into the corresponding Italian school level (14-15 yrs students).

The Italian and Greek educational systems are both centralized; the curriculum is compulsory and established at national level. In both countries, science teaching shares some other important characteristics as, for instance, the low diffusion of hands-on laboratory and ICT based activities and the lack of habits of inquiry teaching on behalf of teachers. Moreover, concerning the scientific contents addressed in the curriculum at lower secondary school level, basic aspects about heat and temperature phenomenology, heat conduction and some ideas about the matter structure, e.g., atoms and molecules, are addressed in both countries.

The specific purpose of this study is therefore to investigate to what extent such similarities between the educational systems of the two Countries have favoured the transfer of an educational practice which has been proved to be successful in the original context. In particular, the specific research questions that guided this study are:

RQ1) was the original TLS changed in the process of transfer in the new context?

RQ2) what were the similarities between the educational systems that favoured (or influenced) the embedment of the original TLS in the new context?

RATIONALE

A simple way to transfer knowledge organized in the form of a TLS would consist in a unidirectional adaptation from the original educational context to the host one: this linear process would occur mainly when TLSs are edit in such a format that makes difficult any flexibility. However, previous studies in Science Education (Pintò, 2005) have shown that TLSs, in particular those aimed at innovating usual teaching habits, cannot simply transferred from the original designers to the users (scholars, teachers, …) but re-made, re-constituted, and re-structured. To put it simpler, the actions that will take place in order to adapt the original teaching proposal to the context in which it will be actually implemented are unavoidably transformative. Hence, from a general perspective, knowledge transfer of a research-based TLS is not an unilateral process from a developer to a passive receiver since a TLS necessarily involves both explicit artefacts containing formal knowledge and tacit knowledge related to designing and implementing it.

To take into account the complexity embedded in the TLS transfer process, we opted to frame this study into the "*Adaptation* and *Re-Invention"* (ARI) model (Rogers, 1983). Within this model, a basic transfer process consists in a bi-directional communication between two main "actors", namely the original knowledge producer and the host one. During the communication process, the two actors reach a consensus about the adaptations and refinements that the original product must undergo in order to fit the host context (Figure 1).

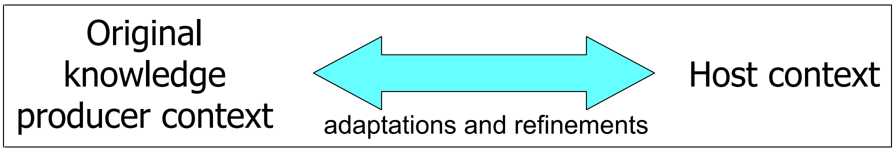

Figure 1: graphical representation of the basic ARI model (Rogers, 1983)

In the case of the transfer of a TLS, we conceive the process as an interactive cycle consisting in a de-contextualization of the original implementation procedures, the identification and adaptation of general "core" ideas embedded in a TLS, and a re-contextualization in the new setting (Figure 2).

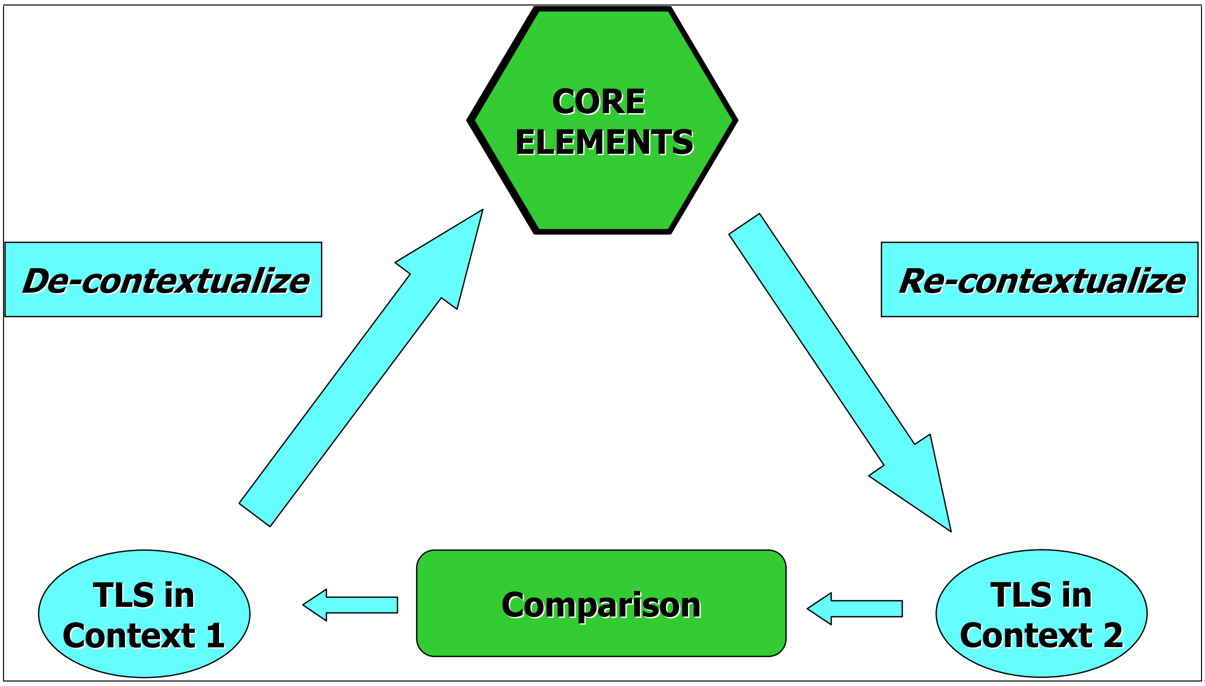

Figure 2: graphical representation of the modified ARI model to frame TLS transfer process

Briefly speaking, we suggest that the core ideas of a TLS materialize in specific elements concerning the scientific concepts and models addressed, the pedagogical approach used in the activities, and some ICT-enhanced aspects. Not all elements in original TLS are core ideas, of course: for instance, some specific activities or particular experiments cannot be included in the core, unless they are considered essential for the conceptual sequence of the overall TLS. The envisioned process is essentially research driven: data (original and host designers' views, involved teachers' actions and ideas, students' achievements) are collected in both contexts during the overall transfer process. In particular, content analysis "in retrospective" of the data collected in the host context allows to compare if the core elements of original context in the re-contextualization phase have been modified, kept or removed. Possible factors that have favoured or hindered the transfer can in this way be reliably identified. Within the proposed modified ARI model, the original TLS is therefore transferable if the whole process does not affect radically its core elements.

For the specific case reported here, the TLS to be transferred was aimed at the understanding of scientific concepts and models related to heat conduction and thermal properties of materials (Hatzikraniotis et al., 2010). Proposed teaching units are based on the Predict-Observe-Explain (POE) strategy (White & Gunstone, 1992) and are aimed at familiarizing students with scientific inquiry, specially improving their capability to design experimental investigations, to verify or reject a hypothesis and to become familiar with the use of experimental evidence. An ICT enriched learning environment is adopted to exploit didactically reconstructed microscopic representations which depict thermal interactions in iconic, graphic and symbolic forms. During the TLS activities, students work in groups, solve problems, and are engaged in classroom discussions with the aim of constructing links between evidence and explanations. The main "core elements" of the original TLS are resumed in Table 1.

Table 1. Core elements of the original TLS on heat conduction

Core Element	Description
Pedagogical approach	Guided inquiry Experimentation from teacher led towards more open investigations, Application of POE strategy based on autonomous group work Design of experiments by students Meta-cognitive reflections within units and overall at the end of the TLS
Modelling	Deductive use by students of simulated microscopic teaching models for visualizing and interpreting temperature and thermal conductivity. Engagement of students to guided explorative modelling activities and reflections on the nature and scope of scientific models.
Scientific concepts	Heat and temperature, heat conduction in materials, behaviour of thermal insulators and conductors (ceramics and metals), microscopic model of matter, factors affecting conduction
ICT	Use of simulated microscopic models of temperature change and thermal conduction in ceramics and metals Use of a virtual laboratory and simulated Flash-based experiments
Other aspects	Combination of virtual and hands on experiments Use of exemplar experiments on thermal conduction in metals Interplay of macro- with micro-processes, conductivity in containers and bars Thermal insulation of a house

METHODS

The transfer process was designed as following. The original developer of the TLS, the Greek group, prepared and provided the host partner, the Italian group, with a “background” document including, in concise form, the formal knowledge of the artefact, contextual information, the specific school settings, relevance of TLS with the local curriculum, and information about the design and implementation of TLS, namely, design principles, the pedagogical approach, the methodological framework, the student assessment tools and the procedures used to apply the TLS. Then, internet based communication (e-mails exchanges, file sharing, etc…) followed, with the aim of enhancing interactions and mutual understanding between the two groups. As a third step, the Italian group prepared a new background document in which information about the educational context where the TLS would have been implemented and the adaptations carried out were provided. Comments and reflections were also given as a sort of feedback to the original designers. As a forth step, two “study visits” followed, involving both developer and host groups experts. One external expert also participated in both visits. Each visit lasted one week and was aimed at analysing the process of implementation and validation of the TLS in both educational contexts. During the visits, at least one implementation in a real school context occurred and data were collected, including for this specific case: experts’ observation notes; interviews with local teachers and students; notes on discussions between researchers and the external expert, students’ pre- and post-questionnaires. As a fifth step, after each visit, the visiting experts prepared a report on the basis of the data collected during the visit, so to give feedback about the feasibility of the TLS to the original designers and about the effectiveness of introduced changes to the partner that adapted the TLS.

The primary source of data for this study were the background documents and the study visit observations, discussions and reports as well as some students' learning outcomes. In particular, evidence to investigate the feasibility of the TLS transfer was drawn from the comparison between the core elements of the original and adapted TLS, resulting in the identification of those elements that have been more easily adapted or transferred from one educational context to another, as well as of favoring and hindering factors.

FINDINGS

The main adaptations introduced by the Italian group and their justification/interpretation are reported in Table 2, according to the adopted core elements analysis.

Table 2. Core elements of the transferred TLS on heat conduction

Core Element	Description (D) and justification (J) of the change(s)
Modelling	*D.* Additional use of mechanical analogies for justifying particle interactions in ceramics and metals *J.* To facilitate students' interpretation of the heat transfer mechanism
Scientific concepts	*D.* Quantitative relationship amongst the factors influencing thermal conduction *J.* The formalization seemed necessary because Italian textbooks at lower secondary school level usually formalize physics laws in a mathematical way. Moreover, it is usual to collect experimental data to prove studied laws
Other aspects	*D.* Changes in the conceptual sequence, e.g., *a)* problematic situation about house insulation addressed at the beginning of TLS; b) introduction of all factors affecting heat conduction before microscopic model *J.* a) House insulation can be motivating for students and an unifying thread for all the proposed activities; b) improve the understanding of macroscopic behaviour may allow for a better justification of the microscopic interpretation

Data about students' achievements have also been collected. Analysis of results after the implementation in a Greek context has been already reported (Hatzikraniotis et al., 2010); preliminary data from the Italian implementation with about 20 students show that, as far as the students' achievements about the addressed contents, the results of the post-test are significantly different from those of the pre-test. A complete quantitative analysis of students' learning outcomes after the implementation of the TLS in the Italian context and the comparison with the results obtained in the Greek context will be reported in a forthcoming paper.

DISCUSSION AND CONCLUSIONS

Taking into account the introduced adaptations, the original designers agreed that the transferred version of the TLS has kept certain essential features of the module in terms of the core elements, as for instance, the use of a guided inquiry approach, the POE strategy, the adoption of a combination of virtual and hands-on experiments and the ICT-enhanced visualizations of microscopic model of matter. The adaptation of the overall conceptual sequence and the introduction of more quantitative aspects, carried out to better fit the original TLS to the local curriculum, were considered to have not affected the core elements.

In the context of the above evidence, it seems plausible to infer that context similarities such as school settings and educational practice between the Greek and Italian educational systems have plausibly acted as “facilitators” in the transfer process. First of all, the centralization of both educational systems seem to have played a key role: in particular, the fact that thermal phenomena was a content present in the both national and compulsory curricula favoured the implementation of the original TLS in the Italian context in usual school time, not requiring any extra school involvement of students and of the teacher who actually implemented the activities. Moreover, the circumstance that in both systems, at lower Secondary School level, Physics is taught as single subject, has driven the choice of the teacher involved in the actual TLS implementation on the basis of the implicit requirement that this teacher should have had a strong content knowledge to correctly exploit some features of the TLS (e.g., visualizations of heat conduction at microscopic level) and to conduct effective laboratory experiments. Also the similarities between the Greek and Italian contexts at the level of pedagogical practices, namely the predominant transmissive teaching approach based on textbooks, the overall weak orientation towards authentic scientific inquiry and the scarce use of laboratory activities, seem to have plausibly helped the transfer process.

Actually, the host group did not need to strongly adapt the proposed activities to the conditions of Italian teaching practice, since the original TLS designers had already taken into account very similar boundary conditions. In a similar way, the school settings (the average number of students per class, the somewhat limited laboratory and ICT equipment), very similar between Greece and Italy, favoured actual school implementations which were highly consistent in the original and host contexts.

In concluding this paper we may note that we have qualitatively described and discussed the transfer of an effective TLS between two educational contexts, the Greek and Italian one, which share some key common characteristics as, e.g.: a centralized curriculum, a general lack of authentic inquiry laboratory practice in science teaching, a traditional teacher-centred pedagogical habit. Basically, the comparison between the original and adapted TLS, carried out in the framework of the ARI model, has shown that these common characteristics have plausible helped the transfer process. This implies that some commonalities in achievements and difficulties when implementing this TLS in these two countries may be expected.

However, similarities are not a sufficient condition for successful transfer, as it has emerged looking back at the whole process. We consider that designers’ shared science education research framework has also played an important role since common views about pedagogical strategies as guided inquiry, POE, modelling and ICT-based interventions, speeded up the process of de-contextualization and re-contextualization of the core elements of the original TLS. In the future, supplementary analysis of the overall transfer process, documented by means of different data sources, will provide additional insights to scholars interested in the more general problem of transferring effective practices across different European countries.

ACKNOLEDGMENTS

The work presented in this paper was supported by the European Union through the European Communities Research Directorate General in the project **Materials Science – University-School Partnerships for the Design and Implementation of Research-Based ICT-Enhanced Modules on Material Properties**, Science and Society Programme, FP6, SAS6-CT-2006-042942

The authors want to thank prof. M. Meheut for her contributions during the different phases of the transfer process

EVALUATION AND ASSESSMENT OF STUDENT LEARNING

TOWARDS THE DEVELOPMENT OF A MULTIMODAL, TASK-BASED APPROACH FOR INVESTIGATING CHILDREN'S IDEAS

Carol Callinan[1] and John Sharp[1]

LN1 3DY

Abstract: The constructivist perspective maintains that children will have formed some representations of scientific phenomena in order to understand the world around them (Driver et al, 1994). Resulting 'alternative frameworks' are subject to change when children begin to learn science formally in school (Driver & Bell, 1986). This has led to a wide body of research aimed at identifying and understanding the underlying mechanisms that support conceptual change dynamics (Vosniadou, 2008). Contemporary literature typically accesses conceptual knowledge through verbal reports gained during individual interviews or activities (Primary Space Projects, 1990-1994). Whilst these approaches have been successful in helping to understand what children know and can do this bias towards language and linguistic capabilities at the expense of other forms of communication may prevent a comprehensive understanding of knowledge growth particularly if children are not able to clearly or fully articulate their ideas (Goldin-Meadows, 2000). This paper discusses the development of a new and innovative multimodal, task-based approach to investigating children's ideas in science. The approach utilises highly contextualised practical science activities in order to elicit and challenge existing ideas and incorporates a video analysis of non-verbal gestures and actions. It is suggested that this method provides a more holistic and robust approach for investigating children's ideas and concepts in science.

Keywords: Multimodal research, audio-video research, practical science activities, collaborative group work, verbal and non-verbal communication

INTRODUCTION

Constructivism remains one of the most influential contemporary approaches to understanding how children come to learn science in school classrooms. The constructivist perspective maintains the view that children will have formed some representations of many of the phenomena studied in school science based on their previous experiences and reflection on those experiences in order to understand the world around them (Driver, Asoko, Leach, Mortimer & Scott, 1994). These initial representations are proposed to take the form of 'alternative frameworks' because of the explanatory scope that they provide children with. These 'alternative frameworks' contain conceptual understanding that frequently contrasts with the scientific explanations of the same phenomena and therefore they are subject to change when children begin their formal science education (Driver & Easley, 1978; Driver & Bell, 1986). Research investigating learning from this perspective has led to the development of a number of explanatory models identifying underlying mechanisms that support such 'conceptual changes' (for example Vosniadou & Brewer, 1987; diSessa, 1988; Sharp & Kuerbis, 2006, summaries in Vosniadou 2008; Limon & Mason, 2002). These models range in their depth and scope with some placing a high emphasis on purely cognitive processes

(Rumelhart & Norman, 1978; Posner, Strike, Hewson & Gertzog, 1982) whilst others attribute a strong role to motivational and affective factors (Pintrich, Marx & Boyle, 1993, Dole & Sinatra, 1998). There are significant difficulties associated with the comparison of these models because often the research investigates different participant populations, different domains of scientific knowledge or measures different levels of mental representation. The methodological approaches used during data collection are also subject to criticism, notably because there is a bias towards language-based responses.

Contemporary literature typically approaches the assessment of conceptual knowledge through verbal reports that are accessed through interviews or task-based activities (Osborne & Freyberg, 1985; Primary Space Projects, 1990/1994). Whilst this approach has been successful for generating a wide body of understanding regarding the knowledge that children hold, the bias towards language and linguistic capabilities may prevent a comprehensive understanding of children's knowledge particularly if children are not able to clearly or fully articulate what they know (Goldin-Meadows, 2000). In order to overcome this potential bias, the work presented here investigates the development of scientific ideas and concepts from a multimodal perspective. The multimodal approach to understanding children's learning is a new and innovative research area but one developing rapidly. Initial findings from wider research adopting this approach have demonstrated that during the course of their learning children utilise a number of different expressive modes in order to acquire conceptual knowledge. These modes include verbal dialogue, written pieces, drawings and other expressive art forms and non-verbal communication such as gesture, eye gaze and body posture (Kress et al, 2001). Whilst Kress et al's research focused on how different modes of activity support children's acquisition of concepts in science other researchers (for example Goldin-Meadows, 2000) have investigated the role that non-verbal language such as gesture has in revealing children's existing conceptual knowledge. One early analysis conducted by Crowder and Newman (1993) investigated the gesture and speech of thirteen children who were learning the science concepts associated with seasonal change. The results revealed that some gestures were 'redundant', others served to enhance the ideas expressed through speech, and in some cases gestures served as carriers of scientific meaning that was not present in language. This led Crowder and Newman to conclude that "*as long as ideas outstrip scientific vocabulary, one can expect to see gestures used by elementary science students to carry unstated ideas"* (p.176). This previous research highlights an important role for other responses types such as non-verbal gesture that may be as important to consider particularly if assessments of children's knowledge and underlying learning processes are to be made.

In one summary paper that drew on a body of research investigating different areas of children's problem solving ability Goldin-Meadows et al (1993) suggest that further to revealing actual knowledge the non-verbal gestures of children and their language based response could, when compared with each other, reveal learning processes in action. This is suggested to occur because new ideas and concepts appear to be available to non-verbal communication before they become accessible through speech. Goldin-Meadows et al proposed that stability between speech and gesture characterises a stable understanding of a concept but a mismatch between the two responses types characterises the time in which children are moving between conceptual understandings and using more than one framework of understanding. It was argued that the "*gesture-speech mismatch signals to the social world that an individual is in a transitional knowledge state"* (Goldin-Meadows et al, 1993, p.279). Taken as a whole this research is suggestive that contemporary language based approaches may be insufficient for capturing the processes of conceptual change as they fail to take account of other response types that may be crucial for revealing conceptual knowledge. In order to overcome these problems the work presented in this paper discusses the development of a new and innovative multimodal, task-based approach to investigating children's ideas and concepts in science.

The work presented here discusses an initial analysis of findings from an ongoing doctoral level research project currently in the main data collection and early analysis phases.

RATIONALE

This project specifically investigated the following research questions:

- how and to what extent do multimodal analyses of children's verbal and non-verbal communication facilitate understanding of the science ideas and concepts that children have;
- to what extent can such analyses be utilised in order to explore and understand the dynamics that support conceptual change?

METHODS

This project here utilised a cross-sectional design by studying the scientific ideas and concepts of three groups of children aged seven, eleven and fourteen years in English Primary and Secondary schools. A total of 101 children took part in the study, the children were distributed as follows across the three age groups; 34 aged seven, 44 aged eleven and 15 aged fourteen, with an additional group of 8 Secondary School children (aged between twelve and fifteen) from a school science club. All of the children participating in the study completed two practical science activities, one in electricity and one in floating and sinking. The practical activities were designed to elicit children's ideas by probing understanding as they completed familiar tasks (for example, testing different materials to observe whether they float) whilst subsequent tasks were designed to challenge existing ideas (for example, pushing an inflated balloon into water in order to feel the upthrust force and observe the change in water level). These activities permitted analysis of both existing ideas and concepts and the opportunity to observe the outcome when concepts begin to change or are challenged.

The practical science activities took place in small groups (approximately five children of the same age in each group). The activities were highly contextualised to the concepts studied, interactive and dialogic in nature and included protocols from participant observation and interview based methodologies. Each practical science activity lasted approximately one hour. All were audio-video recorded in order to capture events fully and to obtain gesture in transmission.

In order to explore the potential role of each response type the transcription and the subsequent analysis focused on the modes and areas shown in figure 1.

Levels of Analysis
Analysis of Verbal Responses
Analysis of Drawing
Analysis of Written Responses
Analysis of Gesture and Non-verbal Responses
Analysis of Social Interaction
Analysis of the Activity

Figure 1: The different levels of comparison and analysis explored in the study.

Transcripts coded both verbal and non-verbal responses collected throughout each of the activities. Analyses of the data included both within and between age group comparisons for children's ideas and concepts related to each of the science topics. Verbal and non-verbal data were interpreted using a content analysis approach and analysed in order to capture matches and mismatches between the two forms of communication.

RESULTS

Although this project is still in the early stages of analyses the results are beginning to reveal important information about children's gestures. Our data demonstrates that children's gestures can have three different roles, they can be redundant to the speech, they can support the ideas discussed in speech and they can contain vital clues and cues to children's ideas that are not contained within the verbal responses. These findings are consistent with the previous research discussed above (Crowder & Newman, 1993). For example, the analyses investigating the gestures that the children used when discussing their ideas for electricity following the construction of a simple circuit came in three distinct forms. Some children used one hand to draw a path that began at the battery and followed the wire before stopping at the bulb. Other children used one hand to draw a path that began at the battery, followed the path of the wire to the bulb before continuing around the second wire and stopping at the battery. Finally, some children used both hands to draw a path that began at the battery, each hand then followed a different wire until they met at the bulb and stopped there. This final example is resonant of the 'clashing currents' model discussed in the research literature (Osborne et al, 1991). However, using the children's verbal responses in isolation would not have permitted the identification of these three distinct models. In all cases children's verbal responses contained the same or very similar information and they frequently stated that 'the electricity flows through the wires to the bulb'.

Our results also suggest that the gestures that children produce during our activities appear to fit into five different categories. These gestures contain both scientific and social information which can help us to gain a greater understanding of what children know and can do (Callinan & Sharp, 2011). Figure 2 below provides an overview of the types of gestures identified during the study.

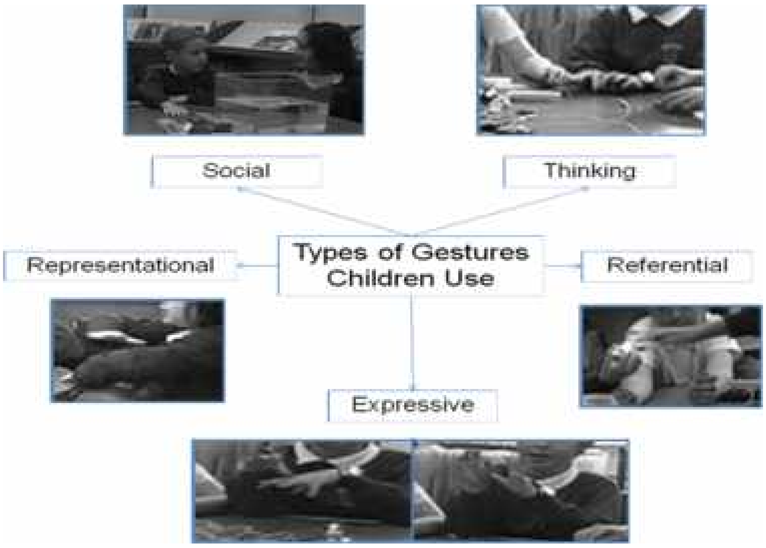

Figure 2: The types of gestures that children use when completing practical science activities and discussing their ideas (Callinan & Sharp, 2011).

Scientific gestures came in four main forms:

- referential – e.g. pointing to objects, pictures or people in the immediate environment;
- representational – e.g. re-enacting the behaviour of objects, the content of pictures, or factors related to people;
- expressive – e.g. often including repetitive movements or building on representational gestures revealing the values associated objects, pictures or people;
- thinking – e.g. finger drumming, waving hands, head holding or face and hair stroking.

The gestures previously discussed which children produced when probed for their understanding of electricity reflect an example of the representational gestures identified. The children used their hands to re-enact the behaviour of 'objects', in this particular example, that 'object' was the 'flow' of electricity within a circuit.

While scientific gestures appear to play a crucial role in facilitating our understanding of children's scientific ideas, social gestures also have an important role for facilitating our understanding of how young children use input from peers in order to structure their responses to probes of knowledge or to seek social support when they are experiencing uncertainty or difficulty in generating a response. During the course of this study there are many instances which demonstrate how children have used such non-verbal approaches to eliciting help from each other. Whilst these gestures can be interpreted as demonstrating little information regarding children's scientific understanding they are particularly helpful for revealing how children negotiate meaning in groups.

Further work will be undertaken to explore how this classification of gestures fit into previously identified categories, for example Kendon's continuum (McNeill, 1992) and Roth (2003).

The match – mismatch analyses of verbal and non-verbal communication further revealed that how non-verbal gestures can contain valuable information regarding ideas and concepts that are not included in verbal responses. For example, analyses of non-verbal gestures produced during the floating and sinking activity revealed that children might be considering variables such as the shape of objects even though such references were frequently omitted from verbal responses.

CONCLUSIONS

The preliminary results to the study support the hypothesis that the multimodal, task-based approach presented here offers a more comprehensive route for studying children's ideas and concepts of scientific phenomena. Notably the study produced evidence that revealed that non-verbal communication such as gesture can contain demonstrations of conceptual knowledge. In addition, a typology of gestures used by children when discussing their ideas for electricity and floating and sinking is proposed. These gestures range from those containing conceptual knowledge to gestures which reveal interpersonal non-verbal cues requesting social support from other children if difficulties are encountered. The comparative analysis suggests that using children's verbal responses in isolation are insufficient and can lead to biased interpretations of what children know and can do. The multimodal task-based approach proved particularly useful for investigating younger children's ideas particularly when they have difficulty in articulating what they know coherently or comprehensively.

[2]Bilkent University, Turkey
[3]Karadeniz Technical University, Turkey

Abstract: The aim of this study was to investigate pre-service teachers' reflectivity and to examine its relationship to their academic performance in a Chemistry Laboratory Course. The participants were 16 second-year pre-service teachers at the Science Education program in an education faculty in Turkey. A combination of qualitative and quantitative research approaches was used in the study. Data on the pre-service teachers' reflectivity was sourced from their learning logs and their academic performance was sourced from end-of-term examinations. In addition, interviews were also conducted with pre-service teachers to determine their views on the effects of keeping learning logs on their learning. According to the results, pre-service teachers exhibited very low levels of reflectivity based on Moon's (2009) classification of levels of reflectivity. There were no indications that reflectivity was related to the teachers' academic performance. However, the interviews conducted with the participants showed that learning logs had a positive effect on their learning, especially when feedback was given. Implications of the results are discussed and suggestions are provided.

Keywords: Reflection, level of reflection, academic performance, learning logs, chemistry laboratory

INTRODUCTION

Reflective thinking has recently become one of the most popular issues in teacher education. Reflection is based on progressivism, which is rooted in pragmatic philosophy. Dewey, who is the pioneer of this philosophy, considered reflection as a special form of problem solving, through careful ordering of ideas linking each with its predecessor to resolve an issue (Hatton & Smith, 2006).

Reflective learning approach encourages active and responsible learners. It gives learners an opportunity to make their own decisions and reflect about their experiences. Thus students become aware of their actions and learn through experience (Wilson & Wing Jan, 1993; Tok, 2008).

In traditional learning approaches, informative role of the teacher makes the students dependent on the teacher to correct their errors. Therefore, the students don't participate in the learning process as decision makers. But in the reflective learning approaches, students can set their own learning goals and they can take responsibility for their own learning (Wilson & Wing Jan, 1993; Unver, 2003).

Various strategies can be used to develop reflective thinking, these are: writing for learning, concept mapping, questioning, self-questioning, negotiated learning and self- assessment (Wilson & Wing Jan, 1993).

This study deals with writing for learning. The act of writing has a positive impact on students' learning. By writing, students understand how to adopt their prior knowledge with their new information and they think about what they know (Gunel, Kabataş Memiş &

Buyukkasap 2009). Studies on writing for learning find are widespread in international literature but in Turkey these are not yet put on the agenda (Gunel, Uzoğlu & Buyukkasap, 2009).

The students' writing can be analyzed in order to define the level of their reflection. For this purpose, Moon (2009) introduced four levels of reflective writing: descriptive writing, descriptive account with some reflection, reflective writing (1) and reflective writing (2).

It is seen that especially in international literature there are many studies dealing with reflection in its various aspects. Among these studies, the number of studies that determine the students' level of reflection (Wong & et all., 1995; Gipe & Richards, 1992; Chalk & Hardbattle, 2007; Sahin, 2009) or that investigate the relationship between the students' reflection level and their academic performance (Chalk & Hardbattle, 2007) are relatively low. Also the existing studies deal with different research areas and there are a lack of studies in pre-service teacher education in this subject. This study will contribute towards the body of knowledge in this area.

The aim of this study is to investigate if there is a relationship between pre-service teachers' level of reflection and their academic performance in a chemistry laboratory course through analyzing learning logs, achievement test scores and their perceptions of the effects of the process on their learning.

METHOD

The participants consisted of 16 second-year pre-service science teachers from a faculty of education in Turkey. All of the participants were enrolled in 'General Chemistry Laboratory III, which one of the researchers in this study taught. The class met once a week for a two-hour section. The data for the study were collected from participants' learning logs, end of term exam scores and semi-structured interviews.

Learning logs were used for defining participants' reflection levels. At the end of the first laboratory section, participants were informed about their assignment. This study uses two-column writing, which is one of the types of writing in a reflective environment. Participants were asked to write the information they learnt from the activity on the left side of a page and to record their personal reactions and reflections on the right side of a page. The left side of the assignment was called the 'summary' section and the right side of it was called the 'learning log' section. They were told that there was no limitation to the number of pages. They were also told that the assignment wasn't going to be evaluated officially and that it would only add to their own learning.

At this stage, 16 pre-service teachers volunteered to prepare the assignments. The participants were asked to prepare one learning log for every two weeks. When the first assignments were controlled, it was understood that the participants didn't understand what was asked of them. Some of them wrote the subtitles of the subject on the summary side and what they learnt on the learning log side. The real aim was restated to the participants as feedback for these papers and some guiding questions were added to the learning log section. These made the participants better understand what they were required to do. Therefore, these papers were not evaluated. Otherwise the first assignments, participants were asked to prepare 5 assignments. Most of the participants didn't complete the number of assignments. These participants were not forced to complete more assignments.

Each participant's learning log was examined and graded from 1 to 4 in accordance with the reflection levels determined by Moon (2009: 67-69):

"Descriptive writing: This account is descriptive and it contains little reflection… Ideas tend to be linked by the sequence of the account/story rather than by its meaning… Most points are of equal importance.

Descriptive writing with some reflection: This is a descriptive explanation that gives some reflection signals but does not actually show much reflection… It focuses on the event as if there is a big question or there are questions to be asked and answered… Asking the questions makes it more than a descriptive explanation, but the inefficiency in responding to the questions means that there is little actual analysis of the events.

Reflective writing (1): There is definition but there are reflective comments for some special focuses… The explanation contains some analysis and the importance of explaining motives or reasons for behavior is realized… There is some self-questioning and a also willingness to recognize the overall effect of the event on himself/herself.

Reflective writing (2): There is clear evidence of thought and internal dialogue when the event is reversed. The explanation contains deep reflection, and it incorporates an awareness that the frame of reference with which an event is viewed can change. A metacognitive stance is taken… It is observed that learning is realized from experience and points which are written for learning."

Two writers of the study was analyzed all participants' learning logs independently.

To examine the categories' reliability correlation coefficient was calculated between the two writers' rating. A correlation of 0.93 ($p<.01$) was found which indicates a strong, positive and statistically significant relationship. Since the writers' rating of participants' learning logs were close to each other it can be said that inter-rater reliability for the categories was high.

The reflection level of each participant was found by taking the mean average of all of his/her learning logs. An end of term exam was used as the determiner of the participants' academic performance. All of the exam papers were evaluated by using an answer key. According to the answer key, the maximum points that could be gained from this exam was 100 and the minimum was 0. A correlation coefficient was calculated in order to measure the degree and the direction of the relationship between the pre-service science teachers' academic performance and their reflection level.

Semi-structured interviews were carried out with 9 of the teachers to find out what effect the learning logs had on their learning. The interviews were conducted with participants who prepared 3 or more assignments and volunteered to conduct interviews. The data collected from the interviews underwent content analysis. Additionally we examined one of the participants as a case study which we thought that her statements give more information about the effectiveness of the reflection process.

A single unique identity number was generated for each participant. Names were not used. A nickname was given to just our case.

FINDINGS AND DISCUSSION

In this section of the study, data collected from the participants' learning logs, achievement tests and interviews are presented. This section is presented in three parts. In the first part, the reflection level of the pre-service teachers is determined and the relationship between their academic performance and reflection level are examined. In the second part of the study pre-service teachers' ideas about the reflection process is determined and in the third part one of the participant's responses is examined as a case related to the data obtained from the interviews.

The Relationship Between Academic Performance and Level of Reflection

The table below provides the data on the pre-service teachers' levels of reflection and the relationship between their levels of reflection and academic performance.

Table 1. The relationship between the pre-service teachers' levels of reflection and academic performance

Student	Reflection level							
ID	Assignment number							
	I	II	III	IV	V	Number of assignments	Sample mean	Exam mark
1	3	2	2	2		4	2.25	47
2	3	3	1			3	2.33	9
3	2	1		2	2	4	1.75	26
4	2	1	1	2		4	1.5	93
5	1	1	1			3	1	19
6	1	1	1			3	1	31
7	2	2	2			3	2	15
8	2	2		1	1	4	1.5	27
9	1	1	1	1	1	5	1	10
10	2	1				2	1.5	16
11	2	2	1			3	1.67	37
12	2	2	2	1	1	5	1.6	11
13	2	1	1			3	1.33	5
14	1	1	1			3	1	26
15	1	1	1	1		4	1	37
16	2	2	2			3	2	42
							Correlation	.07

In table 1, the numbers in the first column represent the study participants and the
Roman numerals represent five assignments completed by the participants. Each learning log of the participants' was graded from 1 to 4 in accordance with the reflection levels determined by Moon(2009)'s categories. Analyzing the table, it can be seen that no learning log earned 4 points and that 53 out of 56 writings that pre-service teachers produced fall under the category of "descriptive writing" or "descriptive writing with some reflection" as described by Moon (2009). Only three writings from two participants had some evidence of what Moon called reflective writing (1). In her study, Sahin (2009) also examined 20 pre-service science teachers' reflective thinking ability according to their weekly journals; similarly, she determined that their descriptive reflectional thinking ability was more dominant. She also pointed out that pre-service teachers' critical reflective thinking ability was less developed and that some of them totally lacked it.

Table 1 also represents the number of assignments prepared by each pre-service teacher and their average reflection levels and the exam scores. When the participants' exam scores and reflection levels are examined together, a correlation of .07 was found, indicating that there is no relationship between reflectivity and academic performance. In a similar study Chalk and Hardbattle (2007) carried out with 15 science and engineering students, they found a positive, weak correlation between the students' academic performance and their reflecting writing scores.

The reason that there is no connection between the pre-service teachers' reflective writing scores and academic performance could be that so many of the participants' reflection levels were so close to each other. Another reason could be that participants did not complete their all assignments. In this study, participants were expected to prepare 5 assignments but even though all of the participants volunteered to take part only two of them completed their assignments. Therefore, the need to examine the correlation between the reflection scores and the performance of the participants who prepared 4 or 5 papers was felt. The obtained data is given in Table 4.

Table 4. The correlation between academic performance and the level of reflection

ID	Number of assignments	Exam mark	Reflection level
1	4	47	2.25
3	4	26	1.75
4	4	93	1.5
8	4	27	1.5
15	4	37	1
9	5	10	1
12	5	11	1.6
		Correlation: .2	

In this situation a weak correlation of .2 was found between the reflection scores and participants' academic performance. The correlation was not significant but the increase in the correlation supported our thinking that if the participants had completed all their assignments the results could have been different.

Pre-Service Teachers' Ideas About The Reflection Process

Semi-structured interviews were conducted with 9 of the participants to learn their views about the effect of learning logs on their learning. Analyzing the data from the interviews, pre-service teachers opinions were put into three categories.

Table 2. Pre-service teachers' views on the effects of learning logs on their learning

The effect of learning log on learning	f	ID	Number of assignments
Learning logs are effective on learning the subject when teacher gives feedback.	5	3	4
		6	3
		5	3
		4	4
		8	5
Learning logs are effective on learning the subject.	1	12	5
Learning logs are not effective on learning the subject.	3	2	3
		14	3
		1	4

In the first column of table 2, teachers opinions are presented and in the second column of the table the number of participants who attended in each category are presented. Three out of nine participants stated that preparing learning logs was rather entertaining for them and helped them to relax but they also noted that it had no effect on their learning. The other 6 participants stated that learning logs were effective for their learning. However, when the table is examined, it can be seen that these participants are separated into two groups. Five of them stated that without feedbacks the logs are not effective on their learning. Only one participant stated that learning logs are effective on learning whether there is feedback or not.

8 out of 9 participants who took part in the study couldn't see a direct connection between learning and preparing learning logs. One reason for this can be that the participants had come across such an application for the first time. The aim of learning logs is to develop students' metacognitive strategies (Ozsoy, 2008). However; metacognitive learning strategies (planning, controlling, managing) have no direct effect on the operating process (Tascı et al,

2008). Namely, participants' academic performance is expected to improve as a result of using skills such as planning, controlling and managing learning which are expected to develop as a result of reflective applications. Within this scope, it can be said that it is natural for the participants who have come across such an application for the first time could not benefit from the application or not be able to realize or express this indirect effect.

Also only 2 out of 9 participants prepared 5 learning logs. The other participants prepared fewer assignments. The participant who believes that preparing learning logs is effective on learning is one of the participants who prepared the most logs (5 logs). When the time of the application is extended, the pre-service teachers can better analyze the effect of preparing learning logs on themselves.

Case Study

Elif. This part of the study examines Elif (ID 12) as a case study. Elif is one of the participants of the study who completed all of the assignments and the only participant who found preparing learning logs effective on learning whether there is feedback or not. We thought that her statements give some insights about the effectiveness of the reflection process. The following quotation shows that she really understood what a learning log is:

> *"I can establish a relationship between the level of learning and the right side of the paper. I mean, at the evaluation stage the student already knows what she has learnt, what she can and can't do; in short she can see herself like the reflection of a mirror… The student can exactly see himself/herself and this vision directly affects his/her learning".*

Even if Elif's learning logs did not enhance her success at the end of term exam results, the data obtained from the interview carried out with her showed that they contributed to Elif taking responsibility for her learning and also gives some information about the process of keeping learning logs.

Elif explained that she accepted to attend the implementation because she found the General Chemistry Laboratory III course content difficult and she did not know how to study it and thought that it may be a solution for her to pass the course. But she said that, firstly she couldn't understand what the instructor asked them to do that is why this was the first time that they asked to keep a log for a course. And she added that even though she was a volunteer, she did not pay much attention to her first assignments and did not study the course. Then she continued that the assignment feedback helped her to understand how to do it and also directed her to study more:

> *"At the beginning I used to say that I can't do it and put it aside and the reasons were that I didn't attend the lesson and I didn't have any preparation for it too… The more you write me (give me feedback) I started to ask myself why do I not study… I mean this made me study better…"*

She also stated that she started to prepare learning logs for other courses. With formative evaluation the students' special problems in their studies are dealt with and feedback is an important part of it. Even if it is beneficial for all students, it is especially effective for students whose level of success is low (Black and William, 1998). In this case Elif may have gained awareness about her learning responsibility because of a teacher who gave feedback to her.

CONCLUSIONS AND RECOMMENDATIONS

The study aimed to determine whether there is a connection between reflection levels of pre-service teachers and their academic success. At the end of the study it was seen that none of the reflection levels of the pre-service teachers went beyond description; namely, they couldn't reach the level of reflection. Therefore; the application couldn't create a difference in the academic success of the participants which was determined with an exam. However; even though it wasn't effective on their exam results, the interviews conducted with the participants showed that learning logs had a positive effect on their learning, especially when feedback was given.

The fact that the pre-service teachers' reflection levels did not go beyond description in this study shows that pre-service teachers who come across the notion of the reflection for the first time need a longer period of time to develop this ability. If the pre-service teachers had reached the level of reflection the effect on their academic success could have been seen more clearly.

As a result, this study is important because it provides data about the reflection level of pre-service teachers. However, it is a small scale study and lasted only for a semester, and this may not be long enough for significant changes to take place. Improving pre-service teachers' reflective skills may require longer periods of time. Therefore, further studies could consider training pre-service teachers to develop their reflective skills over a longer period of time and possibly use longitudinal studies to monitor its effects on learning. In addition, as it is the case for all social studies that use human beings as the sample, participants' unique characteristics and physical and other conditions may always affect the results. Thus, there is a need for replicating the study with a different sample to verify the results and specify further effects.

USING LARGE SCALE TEST RESULTS FOR PEDAGOGICAL PURPOSES

Jens Dolin[1]
[1]Department of Science Education, University of Copenhagen, Danmark

Abstract: The use and influence of large scale tests (LST), both national and international, has increased dramatically within the last decade. This process has revealed a tension between the legitimate need for information about the performance of the educational system and teachers to inform policy, and the teachers' and students' use of this information for pedagogical purposes in the classroom. We know well how the policy makers interpret and use the outcomes of such tests, but we know less about how teachers make use of LSTs to inform their pedagogical practice. An important question is whether there is a contradiction between the political system's use of LST and teachers' (possible) pedagogical use of LST. And if yes: What is a contradiction based on? This presentation will give some results from a systematic review on how tests have influenced the pedagogical practice. The research revealed many of the fatal wash back effects known from other research but gave additionally some insight in teachers' attitudes towards LSTs. To account for these findings results from another research project - the Validation of PISA – will be included. This project analyzed how PISA has influenced the Danish educational system and the different theoretical foundations of PISA and most teachers' pedagogically oriented, formative assessment, thus explaining the teacher resentment towards LSTs. Finally, some principles for linking LSTs to teachers' pedagogical practice will be presented.

Keywords: Large Scale Test, formative, assessment, pedagogic, PISA

BACKGROUND AND AIM

Testing of pupils' knowledge and skills in schools has been common practice in many school systems for a long time. However, the format and the purpose of this testing has shifted across time and across systems as it has increased in its scope and extent. An overall explanation for this growing interest in large-scale tests may be found in the increased globalization and marketization of the educational system forcing policymakers to find tools for gathering information about their own system's performance. This is given precise expression in the statement from PISA (OECD, 2004) that:

Across the world, policymakers use PISA findings to:

- *gauge the literary skills of students in their own country in comparison with those of the other participating countries*
- *establish benchmarks for educational improvement …*
- *understand the relative strengths and weaknesses of their educational system.*

However, there is enormous variation in how assessment is conceptualized and operationalized in different educational systems and even within the same system. Even though the primary purpose of mandated testing in most educational systems ostensibly serves the function of increasing the quality of teaching there are different emphases. As such this is a reflection of the different weighting of specific goals. For instance whilst some systems emphasize the purpose of monitoring the system using tests based on representative samples of students in selected grades and in selected subjects (e.g., Finland and New Zealand), other systems highlight the use of tests for accountability purposes requiring that all students are tested for the purpose of reporting indicators of performance at the sub-system and school level (eg. UK and Ireland). Other systems, however, develop tests mainly to be used by the teachers as tools for monitoring and improving their own practice (e.g., Sweden and Denmark).

This widespread use of system wide testing of students testifies that policy makers across the world hold a common belief that tests are important agents of change leading to improved quality of schools. But it is crucial to underline that the increase in LST is not due to pedagogical reasons and are not based on teacher formulated needs in classroom contexts, but an overall (and legitimate) political wish for increasing the quality of the educational system. The question is whether there is a contradiction between the political system's use of LST and teachers' pedagogical use of LST. And if yes: Is it possible to harmonize or integrate these two applications of LSTs so they can serve the interests of both policymakers and teachers? However, although we know well how the policy makers interpret and use the outcomes of such international tests, we know less about how teachers make use of large scale tests to inform their pedagogical practice. One first step, then, is to establish what use teachers are currently making of such assessments. A Danish study systematically reviewed all accessible research on how tests influence teachers' pedagogical practice (Nordenbo, S. E., Allerup, P., Andersen, H. L., Dolin, J., Korp, H., Larsen, M. S., Olsen, R.V., Svendsen, M.M., Tiftikci, N., Wendt, R.E. & Østergaard, S., 2009). The method and the main results from this study will be presented below. The results will subsequently be interpreted from two different perspectives. One will explore the political implications of large scale tests in an understanding of teachers' dislike of such tests (Dolin & Krogh, 2010). The second will analyze the different theoretical foundations of large scale tests and most teachers' student assessment (Gipps, 1999; Krogh & Dolin, 2011; Buhagiar, 2007;).

METHOD: A SYSTEMATIC REVIEW OF THE LITERATURE

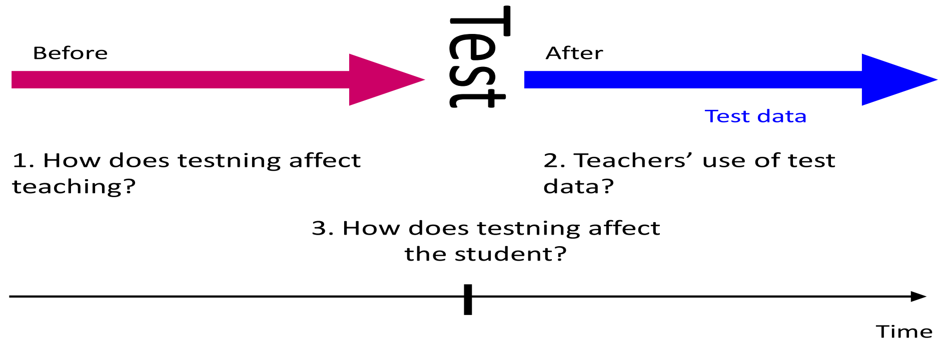
Motivated by newly introduced national tests, the Danish Clearinghouse for Educational Research initiated in 2007 a systematic review (a meta study) of the two questions:

How are tests used for pedagogical purposes by teachers? and

What are their effects on the pedagogical practice?

The author participated (together with three other Nordic researchers and the Clearinghouse staff (including librarians, research assistants etc.) in this review (Nordenbo et al, 2009). It was based on all published research in the period 1980-2008 of how tests had been used to improve the learning process.

A model of the pedagogical process which formed the basis of the review is shown in Figure 1. This article only includes question 1 and 2 from the model.



Figur 1. The research model

The research group narrowed the research questions in an ongoing process to keep the research literature on a manageable level and the final research questions were:

How can primary school teachers' individual and class oriented use of test data enhance teachers' didactical and/or subject specific teaching in classes without special needs students? (Question 2 in Fig. 1).

How does the introducing of tests affect the teachers' didactical decisions (question 1 in Fig. 1) and the students' learning approach (question 3 in Fig. 1).?

The questions only pertain to test types that form part of national tests in the Nordic countries.

Many studies, for instance those relating to documenting effects of introducing tests at a system level, where excluded from the review thanks to this narrowing of the research question, and 5986 references from the first search were cut down to 118 documents of which some, after a more thorough reading, did not fit the criteria. The remaining 61 publications were re-described according to the EPPI Centre data extraction and coding tool for education studies v2.0 (EPPI Centre, 2002). This tool lists 87 categories to describe a research project, covering the project's purpose, context, design, method, results, and research and report quality. For each study these categories were filled in the very fixed template, which makes it possible to extract the research evidence for each category. The tool can be criticised for its relatively rigid approach to research (Bennett et al, 2005) but it gives a systematic overview of the research within a specific area. Based on the tool's quality criteria some publications were excluded and we ended up with a narrative synthesis based on 43 research projects.

RESULTS

Of the 43 studies that met the criteria for inclusion, only 6 studies related explicitly to science (Bauer, Mathison, Merriam, & Toms, 1990; Center for the Study of Testing, 1992; Danmarks Evalueringsinstitut, 2002; Smith, Hounshell, Copolo, & Wilkerson, 1992; Stone & Lane, 2003; Sturman, 2003). Some general characteristics of these studies: five of them were in English, four of which related to state accountability programs in the US, and one paper related to national assessments in England. All of these studies were based on teachers' retrospective self-reporting or perceptions on how one or several tests have affected their teaching. None of the studies in the review (including those from other subjects) addressed the whole chain from testing to improved learning. Given the significance of assessment on pedagogy and curriculum (Au, 2007), perhaps the most interesting, and for us who were involved, surprising result was that the international community of educational researchers seems to be disinterested in this topic, and most of the research identified as relevant to the overall research question posed by the study was classified as being of weak or moderate quality. As the science studies do not differentiate from the total sample, the following results are based on all studies.

The review revealed most evidence on question 1 in Fig. 1, about how the tests as such (i.e. the fact that testing is taking place) affect the teachers' didactical decisions. We concluded, in accordance with the general understanding amongst educational researchers, that:

- tests do affect the teacher's instruction in the intended way, but
- the effects are not uniquely positive, as

The review reveals considerable negative effects of introducing centrally administrated tests:

- a narrowed down or distorted realised curriculum: professional lines of thought are simplified, facts and mechanical skills are emphasized on behalf of creative and aesthetic perspectives
- teaching time allocated to test issues on behalf of not test issues
- teaching becomes addicted to teaching to the test and rote learning

As regards the question of the teachers' pedagogical use of test data (question 2 in Fig. 1) we first realized that none of the studies dealt with the teacher's interpretation of the information embedded in test data. So we really don't know whether teachers understand test results in accordance with the test developers' intentions. One finding to emerge, however, was that the teachers' sense of ownership of the tests seemed to play a central role in 'successful' systems. Teachers prefer tests adapted to the actual class and teachers prefer tests with multifaceted results - but these relations are vaguely investigated in the research literature. One study showed, that the very fact that a test is taken, can completely overshadow the teacher's openness for a pedagogical use of test data.

DISCUSSION

The interesting questions arising from these results are why LSTs are so relatively badly received by teachers and difficult to use pedagogically - and whether they can be designed and used better for this purpose?

One group of answers relates to the way LSTs are introduced and used politically. Teachers often lack sense of ownership to LSTs and as our research showed, this is one of the main factors contributing to teacher acknowledging the relevance of a test and hence opening for a pedagogical use of tests. The tests are designed by others and not suited the teachers' own classroom (for which they compensate by fitting their teaching to the test!). At that, the results of these tests are often used against teachers: Students perform badly equals teachers do a lousy job! This is in many ways an interesting reaction from the political/educational system, a reaction you would seldom experience in other areas of public life. Could you for instance imagine soldiers returning from a lost battle being met with critical comments?
At the same time, test results often have political implication that will affect the working conditions for the teachers. The research project 'Validation of PISA in a Danish context' (http://www.ind.ku.dk/english/projects/) analysed the relevance and consequences of PISA science in a Danish context. The project points out the fact that the PISA2003 results were released Dec 4th 2004 and the Danish government introduced obligatory tests on most levels

Dec 7th 2004. (Dolin & Krogh, 2010). Danish/literacy, mathematics, and all science subjects are now tested, and most tests are placed around the 15-year-old age window. The Danish Teachers' Union tried, unsuccessfully, to rebut the test initiative with results from a survey showing that Danish teachers were already testing in their classes.

Coinciding with such direct implications, LSTs often provide results on a very high level of aggregation, which are used to change a whole system, and hence introducing changes, that neglect facts on lower levels. The PISA2000 report, for example, indicated that larger schools provide for better student performance than smaller schools. These results have impacted the Danish debate where the PISA chief researcher as late as 2007 stated that larger schools (at least 700-800 students) produce better student performance and improve economy (Hvid & Johansen, 2007). Local politicians have been happy to see economical and quality aims coincide, and the conclusion has been used to close a number of smaller and presumably more expensive schools (Brøndum & Fliess, 2007; Hvid & Johansen, 2007) – irrespective of the performance of the specific school. Surprisingly, however, comments in the Danish PISA 2006 report questioned the validity of this conclusion: "PISA 2000 indicated that students in larger schools have better science skills, also when these [were] corrected for relevant background factors, but … this tendency is not statistically significant in PISA 2006" (Egelund, 2007, p. 200).
So, LSTs often influence the general terms as well as the everyday working conditions for teachers in a negative way, for which reason teachers often meet them with opposition.

A more profound reason for teacher opposition to LSTs is the different values inherent in the deeper logic of LSTs and teacher assessment, respectively. Any LST test must be reliable and they are therefore forced to compare relatively simple aspects of student performance, while the (valid) test of advanced competencies are complicated and expensive. Teachers in their daily practice struggle with teaching their student these complex competences so they often find the simplicity of LSTs inappropriate for assessing the results of their teaching. This was reflected in the results from Nordenbo et al (2009) showing that teachers prefer tests with multifaceted results.
Even more profound is the different theoretical foundations of LSTs and most teachers' student assessment. The 'Validation of PISA in a Danish context' – project establishes two different paradigms for assessing students (Krogh & Dolin, 2011), based on different understandings of knowledge and learning. PISA, like all LSTs, sees student abilities as constant across different assessment situations and in this respect is based on a post-positivistic learning understanding. Much teaching, on the other hand, is based on a socio-cultural approach, seeing student abilities as dependent of/linked to the assessment situation (Gipps, 1999). The post-positivistic, psychometric oriented test design, standardized and with high reliability, that characterizes LSTs, is in contrast to most teachers' socio-cultural, hermeneutic oriented assessments, classroom adaptable and with high validity.
Seen in this light, it is not surprising that many teachers have difficulties in using LSTs for pedagogical purposes and even often have hostile feelings against them.

PERSPECTIVES

The more aligned LSTs can be with class room practice, the more likely it is that they can be used for pedagogical purposes. Such an alignment can in principle consist in LSTs being adapted to classroom practice or teacher assessments being transformed into LST results. On the face of it, it seems more accommodating to try to transform formative and teacher summative assessment procedures into LST results.

What is needed, then, is an assessment system, that can give summative results on student level, that can be aggregated to higher levels - for political purposes - and that can be used by teachers for formative purposes.
These systems have not yet been designed in full scale. But many approaches seem possible. You could for instance extract evidence of student performance form classroom works produced during the course (eg. electronic portfolios). This could be done using computer based technologies where substantial research is done to enhance the possibilities for assessing complex competencies. In general, when students are learning online, there are multiple opportunities for gathering data in the course of learning that can be used for assessment.
The possibilities for integrating LSTs and classroom based assessments exist by now. What is needed is research in usable procedures and policy makers daring implement them.

ASSESSING EXPERIMENTAL PROCEDURES THROUGH DIFFERENT FORMATS – A COMPARATIVE STUDY

Markus Emden[1] *and Elke Sumfleth*[1]
[1]University of Duisburg-Essen, Germany

Abstract: Assessing is, next to instruction, one of the two faces of any education-medal. When it comes to assessing achievements in experimentation, there is a lack of instruments that focus on the process-aspects of experimentation. This focus has become compulsory with the advent of most educational standards which emphasise the methodological character of experimentation as opposed to the output generated by it. This study aimed at suggesting and evaluating performance measures that derive from a shared process model of experimentation that is rooted in the SDDS-model and describes experimentation as a basic sequence of three steps: finding an idea or hypothesis – conducting an experiment – concluding from evidence. In the study, students were videotaped while working on three science experiments. They documented their progress in a novel report form and completed three MC-tests related to the scientific themes of the experiments. Performance measures were generated from video and report analyses. The measures from the report format as well as from the MC-tests were investigated with regard to their statistical correlation to the measure from video analysis, which served as a benchmark. Strong positive correlations (r>.65) were considered an indication of suitability as a performance measure. Results show that the report form can capture students' performance adequately provided they have had the time to familiarise themselves with the format. Concerning the suitability of the MC-test, this study cannot draw final conclusions as data were problematic. Preliminary findings suggest that increased efforts in improving the MC-tests might prove fruitful in identifying yet another assessment format for experimentation.

Keywords: experimentation, performance assessment, secondary school, science lessons

RATIONALE

Scientific experimentation probably is one of the most characteristic features of science classes in schools. This can be regarded a logical consequence of experimentation being a core feature of science *per se*. Experimentation is one of science's means to generate new knowledge by 'directing questions at nature and reading its answers from observations' (cf. Planck, 1942). Therefore, it has been prominent in science education since the 19th century (cf. Lunetta, 1998) – but unlike its role in proper science, in science classes experimentation has often not been an addressing of questions at nature. It used to be practiced in a format resembling some kind of chemical "I spy", in which someone (i.e. the teacher) knew the answer and the very method that students were meant to employ in uncovering their 'new' chemistry knowledge. Although this practice has been criticized quite early (cf. Baxter et al., 1992; Dewey, 1910; Lunetta, 1998), it was not before the advent of science education standards, that focus on aspects of scientific inquiry (e.g., NRC, 1996), that this has changed. Experimentation has increasingly been implemented in science classes to advance students' abilities in acquiring and constructing knowledge from experimental evidence. Yet, teachers are still ill equipped with regard to test instruments that help them to assess students' performance in experimentation. The proposed study aims to fill this gap and to provide teachers with a valid tool for performance assessment.

THEORETICAL BACKGROUND

Having to assess students' abilities in inquiry oriented experimentation means to transcend criteria that focus on the correctness of experimental results and to concentrate on the experimental procedure. There have been numerous suggestions how experimentation might be structured (cf. Emden, 2011) but ultimately they can all be brought to match with the basic three steps that are suggested in the SDDS-model (***S**cientific **D**iscovery as **D**ual **S**earch*: Klahr, 2000). This model from instructional psychology suggests that any researcher who encounters a scientific problem, first, needs to find an hypothesis in order to solve the problem. This can happen either by searching a mental representation of all the hypotheses that the researcher can draw from his prior knowledge or might even be triggered by surprising experimental evidence (cf. Klahr, 2000). After this, the researcher will search another mental space (experiment space) for adequate experiments that can be employed in order to solve the problem. Conducting the experiment and observing the results, he then can evaluate experimental evidence and come to a conclusion that will determine his subsequent actions. The SDDS-approach has frequently been taken up by science education researchers and translated into sequences fit for science classes (e.g., Hamann, 2004; Schreiber, Theyßen, & Schecker, 2009). One of these sequences – the NAW-approach (***N**aturwissenschaftliche **A**rbeitsweisen* (The Scientific Modi Operandi): Klos et al., 2008) – suggests to structure the experimentation process thus: (1) Finding an idea/hypothesis – (2) Planning and conducting an experiment – (3) Drawing conclusions from experimental evidence.

This structure is not wholly academic though and has found its way in some form or the other into science curricula throughout the world (cf. Emden, 2011). If, however, the process of experimentation is meant to be a learning goal of science education, there is the need to identify if the goal has been achieved in a performance assessment. Research in the area of experimentation tests and performance assessment reached a climax in the 1990's (e.g., Baxter & Shavelson, 1994). Typically, in these studies students would be confronted with experimentation materials to solve a given task. Procedures to solve the tasks could be narrowly guided emphasising the obtained results (e.g., Kruglak, 1951) or they could be more open highlighting the process of knowledge generation (e.g., Schreiber et al., 2009).

In attempts of convergent validation, performance measures that usually were generated from secondary products of experimentation (i.e. reports) were correlated with measures from paper-pencil-tests. The tests frequently did not operationalise what was understood by 'experimentation' in the same fashion as the performance assessment did (e.g., Comber & Keeves, 1973) or validation of the performance tasks was left out altogether (e.g., Harmon et al., 1997). In studies, that pre-date the era of skill-based teaching, instruments often did not concentrate on methodological approaches to experimentation but regarded technical issues instead (e.g., Tamir & Doran, 1992). If correlations between experimental and alternative measures were reported, the values favoured more open alternative measures (i.e. reports and open-ended questions) against close-ended Multiple-Choice-items (e.g., Baxter et al., 1992; Baxter & Shavelson, 1994). For close-ended instruments the observed correlations tended to not exceed r>.50; as far as open-ended instruments are concerned, lab-report based instruments appear to be best suited for capturing performance as compared to direct observation (cf. Shavelson et al., 1999). There appears to be no study that administers an MC-test which explicitly focuses on a general structure of the experimentation process as suggested above. This might be one reason for the apparent disadvantage of close-ended paper-pencil-instruments.

It follows that there is a lack of empirically validated test instruments that capture students' performance in experimentation in a process-oriented way. Hofstein (2004) suggests to use 'hot reports', i.e. to have students document their experimentation processes while they are happening and not *ex post facto* after finishing the experiment. Translating his experiences to a younger clientele needs to reduce the degree of openness that might be suitable for science students at university but will most likely damage workability at secondary school level (cf. Sweller et al., 2007). Therefore, a report format has been introduced in this study that provides separate entry slots for the three steps of experimentation (find idea-conduct experiment-draw conclusion). In addition, students are reminded at intervals to document their process in the form.

Regarding the administration of an MC-instrument, experience is drawn from studies with a test format which addresses process aspects of experimentation (NAW-test: Klos et al., 2008). Students are introduced to a pair of students who encounter a scientific phenomenon which they want to investigate. Potential ideas, experimental realisations and conclusions are provided and students need to choose between the options (multiple select, forced choice) regarding their correctness in the given situation.

RESEARCH QUESTIONS AND HYPOTHESIS

The suitability of both, the closed-format MC-test and the open-ended report format, was tested in an experimental study by means of convergent validation against performance results from videotaped experimentation phases. The study addressed these two research questions that share one research hypothesis:

Research Question 1: Does an open-ended report form modeled on SDDS measure student performance in experimentation validly?

Research Question 2: Does a closed Multiple-Choice-instrument modeled on SDDS (i.e., NAW-test) measure student performance in experimentation validly?

Research Hypothesis: The surrogate performance measures from the open-ended report form, the closed MC-test, respectively, correlate with $r \geq .65$ with a benchmark measure generated from video analysis.

DESIGN AND METHODS

Aim of the study was to validate two competing measures of performance in experimentation. Therefore, 339 students (M_{Age}=11.51 years, 53.4% male) from academic track and comprehensive secondary schools worked in pairs on hands-on experiments for 20 minutes, which they documented in an open-ended report-form (CR: distinguishing hard from soft water; OF: lowering surface tension of water to free oil from a flask; SS: distinguishing salt from fresh water). In addition, each of the students filled in the multiple choice NAW-test individually, which was thematically coordinated with the experiment. This was done because it is known that the theme of an experimental task has an effect on student performance (e.g., Brown & Moore, 1994), which would arguably be true for paper-and-pencil-based formats.

Students completed three combinations of hands-on experiment, report form and NAW-test in three separate test instances. This procedure takes into account that performance is not stable between several test instances in experimentation assessments (cf. Cronbach et al., 1997; Shavelson et al., 1999). In order to control for potential sequence effects the three

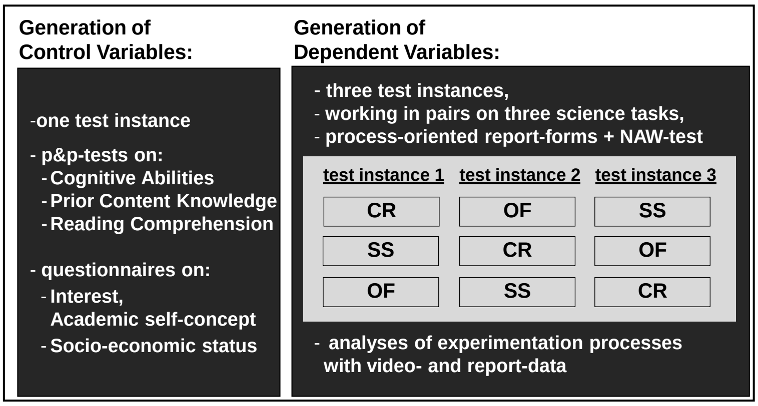

Figure 1 – Study Design

combinations were partially rotated through a Latin square (see Fig. 1). Students were assigned to the experimental conditions on basis of pre-test data from tests on cognitive abilities (Heller & Perleth, 2000) and reading comprehension (Lenhard & Schneider, 2006).

A subsample of students (n_{videos}=98) was videotaped during their experiments. This subsample was distributed evenly between themes of the experiments (CR, OF, SS). The resulting videos were analysed by trained coders focussing on students' demonstration of experimental procedures (cf. Walpuski & Sumfleth, 2009). On basis of the coders' results performance scores were calculated that took into account the directness of the experimental procedure as well as its methodological coherence (cf. Emden & Sumfleth, accepted), i.e. students who went through only one sequence of perfectly aligned instances of finding idea – conducting experiment – concluding outperformed students who needed to go through multiple and/or ill adjusted experimentation sequences (minimum score: 0, maximum score: 10). Correctness of the attained solution was scored in a latter instance and was not included in the process scores. In an analogous fashion, reports were analysed by trained coders and performance scores were determined. The paper-pencil-tests were scored summatively according to students' responses on the forced-choice items. Strictly speaking, only methodological coherence of the experimental procedures could be taken into account as multiple approaches to the experiment were not simulated in the paper-pencil-test.

RESULTS AND DISCUSSION

Reviewing the performance scores of students when working on the experiments from video analysis reveals that, although experiments are relatively difficult for the age group, the method of analysis promises a differentiation between shades of proficiency (s. 'range' in table 1). At the same time, the comparatively low average scores suggest that experiments could be improved to meet the abilities of the age group better, e.g. by reducing the amount of experimentation materials or offering additional aids. This impression can be confirmed in analogous analyses of the report sheets (Emden, 2011).

Table 1 – Performance scores and difficulties for experiments from video analysis

Theme			***M***	**range**	***SD***	**average diffculty ($\bar{P}$)**
CR	total sample	N=32	2.19	0.00–7.50	1.86	.22
	academic track secondary school	n=16	2.14	0.00–7.50	1.78	.21
	comprehensive secondary school	n=16	2.24	0.00–6.25	1.99	.22
OF	total sample	N=30	4.14	0.00–10.00	2.70	.41
	academic track secondary school	n=14	4.73	0.00–10.00	2.99	.47
	comprehensive secondary school	n=16	3.63	1.00–10.00	2.39	.36
SS	total sample	N=36	3.16	0.00–10.00	2.42	.32
	academic track secondary school	n=18	3.26	0.00–10.00	2.50	.33
	comprehensive secondary school	n=18	3.05	.17–10.00	2.39	.31

Analysing the performance scores from video and report-sheet analyses by means of investigating statistical correlation yields the Spearman's Rho coefficients (r_S) detailed in table 2. As can be seen, coefficients for the total sample do not meet the criterion anticipated in the research hypothesis. Yet, when school type is factored in, it becomes evident that the report format is of differing adequacy for students from both school types. While there is evidence in the case of the CR- and OF-experiments (hard/soft water, surface tension) that the report captures the same performance as gained through video analyses at academic track schools (r_S>>.65, p<.01), this is not true for the SS-experiment (salt/fresh water). For comprehensive schools the adequacy of the report format seems to be even reversed, indicating tentative suitability of the report only in the SS-experiment (.50<r<.65, p<.01).

Table 2 – Rank correlations between performance measures from video and report-sheet analyses

		total sample			academic track school			comprehensive school		
		CR	OF	SS	CR	OF	SS	CR	OF	SS
video/report	r_S	.492**	.521**	.383**	.801**	.861**	.294	.348	.300	.510**
	p	.000	.000	.001	.000	.000	.097	.060	.076	.001
	n	60	60	69	30	24	33	30	36	36

The suspicion that the academic track students' higher cognitive abilities bias the observable correlations could not be confirmed in partial correlation analyses (Emden, 2011). Therefore, additional analyses were run that distinguished between the instances in which performance data were collected. The results of these analyses are displayed in table 3; differences in sample size can be explained by exclusion of students from detailed analyses when irregularities in the order of the experiments' administration occurred.

Table 3 – Rank correlations between measures from video and report analyses differentiated by test instance

			test instance 1	test instance 2	test instance 3
academic track secondary school	CR video/report	r_S	.442	.900**	.806
		p	.234	.000	.053
		n	9	10	6
	OF video/report	r_S	1.000**	1.000**	.789**
		p	.	.	.002
		n	4	5	12
	SS video/report	r_S	1.000**	.783**	.293
		p	.	.004	.356
		n	6	11	12
comprehensive secondary school	CR video/report	r_S	.224	.028	.825**
		p	.562	.943	.006
		n	9	9	9
	CR video/report	r_S	-.357	.225	.866*
		p	.192	.532	.026
		n	15	10	6
	SS video/report	r_S	.649*	-.597	.944***
		p	.047	.068	.000
		n	10	10	11

Taking into account that a reduction in sample sizes affects the observable level of significance and compensating this by including $r_S \leq .10$ into the discussion, two tendencies can be seen in table 3: (1) For the CR- and OF-experiments there is a movement to stable and strong correlations over time; (2) for the SS-experiment, at academic track schools the correlations decline over time while at comprehensive schools there is irregular development.

The stabilizing movement might be explained by reference to Cognitive Load Theory (cf. Sweller, 2010) and the imposition of extraneous load. Since both the survey methods (open experiment and process oriented report) were novel to the students, it can be argued that operating both the methods imposes an increased extraneous load at the beginning. Only over time, by familiarisation, it becomes possible for the students to act freely in the methods and finally to align them, so that both the methods capture the same performance.

The decline of correlations in SS at academic track schools might be attributed to a mechanism akin to the Expertise Reversal Effect (Kalyuga et al., 2003). Since an increase in expertise, i.e. growing familiarity with the methods, coincides with the gradual decrease of observable correlations, it might be argued that having overcome initial inhibitions students feel overly self-confident about their abilities and operate the methods with less care. As this interpretation relies on a single case, its character is admittedly rather speculative.

Finally, the test scores from the NAW-tests were correlated with the performance scores from video analyses. Analyses could reasonably be run only with the test for the CR-experiment, since psychometric properties proved to be acceptable for this test instrument only. The observed correlations are displayed in table 4.

Table 4 – Rank correlations between performance measures from video analyses and NAW-test (MC)

		total	**academic track school**	**comprehensive school**
video/NAW (CR)	r_S	.313*	.491**	.202
	p	.015	.006	.283
	n	60	30	30

It can be seen that the anticipated criterion of r_S>.65 is not met in any sample. This means that the hypothesis of the NAW-test being a suitable surrogate for direct observation needs to be rejected. Investigating the reasons for the low correlations more closely, however, gives rise to the idea that principally the NAW-test might be a suitable instrument. With regard to the observed average difficulty of the experimental task, the test items respectively, it becomes obvious that both the instruments lie at opposed ends of the difficulty scale ($P_{experiment}$≈.20; P_{NAW}≈.80). This means that while working successfully on the experiments is very difficult for the students, solving the test items is considerably easier; correlations between thus differently sensitive instruments cannot reasonably be expected to be positive and strong. Additionally, reduced reliability coefficients hint at a less systematic survey than anticipated, therefore, detection of systematic correlations is inherently hindered. Taken these two aspects into account and honouring the fact that, again, this interpretation relies on a single observation, it is possible that, provided the psychometric properties of a test are good and its difficulty is more aligned with the connected experiment, MC-tests might after all be capable of measuring students' achievement in experimental processes. Even as it is, correlations between the NAW-test and the CR-experiment are of a medium strength for academic track students, which promises potential for improvement when using more reliable instruments.

CONCLUSION

This study aimed at identifying instruments that can be used to assess students' achievements in experimentation with a focus on the process. It, therefore, employed a shared process model of experimentation in all the administered instruments and controlled for known influences (e.g., theme, sequence, repeated measures). Analyses could confirm that open reports are favoured as surveying instruments over closed MC-tests. It could be shown, too, that students need time to master the open report format before it can serve as a substitute. Data for the closed MC-tests suggest that there is potential in using these tests as an alternative assessment but psychometric quality needs to be controlled more thoroughly as well as the adjustment to the level of difficulty between competing measures. These findings are in line with earlier work by Shavelson (e.g., Baxter & Shavelson, 1994; Shavelson et al., 1999) but add the perspective of an analysis oriented at a process model of experimentation, which so far has not been respected strictly.

Abstract: PISA report concerning the acquisition of science competences by adolescents of several countries in the world, including Argentina, revealed alarming results. These results led us to wonder: What happens at university level in Argentina?

The results of this paper show what science competences students have when they start attending the School of Biochemistry and Biological Sciences at Universidad Nacional del Litoral (first year of the Biochemistry and Biotechnology courses) in Santa Fe (Argentina) and what competences they have when they finish university (fifth year of the same courses) for their professional integration into the labour market.

Two questionnaires were designed to gather data. One of them was an adapted version of PISA tests and was used to learn about the students' science competences; the other one was used to examine the influence that certain contextual factors might have had on academic performance.

Analysis instruments were also designed for the transformation and categorization of the data in order to find regularities in the competences and in the contextual factors.

From the results obtained in this research, it has been possible to identify: the scientific competences which students have when they enter and leave, as well as the similarities and differences between them; certain characteristics in the university *currícula*, concerning mainly the Chemistry courses, which could provide guidance on priorities for a qualit y education that fosters the development of researched competences; and some of the socio- cultural context factors that influence student's performance in science.

Keywords: science competence, university education.

BACKGROUND, FRAMEWORK AND PURPOSE

Nowadays, science education is expected to provide scientific knowledge, the appreciation of the importance of the contribution of science to society and a more effective preparation of our young students to participate fully in society. To achieve these aims, a critical attitude and a reflective approach to science are vital (Millar and Osborne, 1998).

PISA 2006 assessed different competences but focused on *Science Competences* and highlighted the need to develop innovative teaching approaches which would contribute to the enhancement of education quality. It also emphasized the need to centre on how and with which aim this knowledge is used (OCDE, 2006).

Thus, PISA focuses mainly on scientific literacy rather than on the command of curricular content (Bybee, 1997; Harlen, 2002); that is to say, it gives more value to the ability to solve problems than to memorize knowledge.

Argentina participated in PISA 2006 as a partner country together with other 56 countries. The results obtained by Argentinian young people (15 years old) were alarming. Argentina ranked 51st, obtaining 391 score points, significantly below the OECD average of 500 score points (OCDE, 2008). In the more recent 2009 study, Argentina participated with other 64 countries and the results indicated a negative evolution. In the assessment of science competence, Argentina ranked 56th, obtaining 401 score points, significantly below the OECD average of 501 score points (OECD, 2010).

Having said this, we agree with Monereo *et al.* (2009) that it is necessary to improve our education system. Analysis of PISA results can provide the opportunity to do so. Therefore, it seems to be relevant to carry out research into what happens at university level in Argentina

Rationale

In the new *currícula*, competence-based education and the learning context have assumed major importance. Therefore, the **aim** of this research is to study what science competences students have when they start attending the School of Biochemistry and Biological Sciences at *Universidad Nacional del Litoral* (first year of the Biochemistry and Biotechnology courses) in Santa Fe (Argentina) and what competences they have when they finish university (fifth year of the same courses) for their professional integration into the labour market. To examine whether students have acquired those competences, their capacity to reorganize what they have learnt and transfer that knowledge to new situations and contexts will be assessed (Perrenoud, 2004; Zabala & Arnau, 2007).

In consonance with the aim stated above, the following **Research Questions** have been posed: What science competences do students have when they start their Biochemistry and Biotechnology courses and which are the ones they have acquired by the time they finish university? What are the similarities and differences between the science competences of the first year students and the science competences of the students who have completed their fifth year in both university courses? What science competences are relevant for the design, implementation and evaluation of quality education? How does the socio-cultural context affect the students' performance in science?

METHODS

Subjects and sample characteristics: a sample of 122 students was studied: 63 students of Biochemistry (47 first year students and 16 fifth year students) and 59 students of Biotechnology (37 first year students and 22 fifth year students). Selection was done based on a stratified sampling design to find homogeneity within each stratum and heterogeneity between the strata.

Data gathering instruments: two questionnaires were designed and students were given one hour to complete them. Information was thus gathered in writing.

- *Science Competence Questionnaire:* this questionnaire was designed by selecting some questions in PISA 2006 and adapting them for university level. Three levels of description and interpretation of chemical knowledge deemed to be desirable from an academic point of view in a variety of situations were examined: microscopic, macroscopic and symbolic. The science questionnaire consisted of 17 questions divided into 2 units: *acid rain* (10 questions) and *caries* (7 questions). Each question was awarded 2 points as a maximum score and 0 point as a minimum. Some of them got a partial score of 1 point. *Cronbach's alpha* was used to measure the degree of reliability of the instruments.

- *Questionnaire about the Context:* this questionnaire was designed in order to get information about the following factors: age, gender (inferred from the subjects' names), hometown, secondary school they attended (the specialized area of study or orientation and whether it was a private or a state school) and their parents' educational background and occupation. The aim was to know whether there were any characteristics of the students' socio-cultural context that may have affected the students' performance in science.

Instruments for the analysis of the information: it is understood that people have different degrees of *science competence* and that no one lacks this competence in absolute terms. Therefore, results have been grouped together according to the three levels of science performance quantified by Biggs (2005, p. 236): maximum (100-70 %), medium (70- 50 %) and low (< 50 %). To analyze the performance in *science competences* the baseline was 50% of the total score.

RESULTS

Science Competence Questionnaire:

Scores for each science competence are reported in **Table 1**, together with the percentage of students at each proficiency level. The table comprises the following taxonomic categories: OSP: *overall science performance*; ISI: *identifying scientific issues*; EPS: *explaining phenomena scientifically* and USE: *using scientific evidence*.

Score	% Biochemistry students		% Biotechnology students		Competences
	1st year	5th year	1st year	5th year	
Maximum Level (% score obtained 100 to 70)	0,00	12,50	0,00	9,10	*OSP*
	17,02	43,75	13,51	31,82	*ISI*
	0,00	0,00	0,00	4,55	*EPS*
	6,38	56,25	2,70	22,73	*USE*
Medium Level (% score obtained 70 to 50)	23,4	56,25	2,70	50,00	*OSP*
	42,55	25,00	35,14	31,82	*ISI*
	17,02	37,50	8,11	50,00	*EPS*
	63,83	43,75	64,87	54,55	*USE*
Low Level (% score obtained < 50)	76,60	31,25	97,30	40,90	*OSP*
	40,43	31,25	51,35	36,36	*ISI*
	82,98	62,50	91,89	45,45	*EPS*
	29,79	0,00	32,43	22,72	*USE*

Table1. Students' science performance

As it is shown in Table 1, the number of students reaching the maximum level is very low in all categories. However, at this level, in the 5^{th} of Biochemistry there is a significant percentage in *ISI* and *USE*. In the 5^{th} of Biotechnology the increase is smaller and is associated with a marked decrease in the low level and a constant value in the medium.

Concerning to *EPC*, it should be noted that only 4,55 % of students in the 5^{th} of Biotechnology, having been trained for five academic years, reached the maximum level in the category of *Explaining phenomena scientifically*.

If we focus on students of 1^{th}, the data are devastating, with high percentages of students below the basic level set, except for *USE* where the highest percentage is in the medium level.

In relation to the *OSP*, only the half of the students, near to be professional, achieves the average level established.

Questionnaire about the Context:

For the sake of brevity, the tables with the corresponding data are not included. Data on the subjects' socio-cultural level and background was classified into the following taxonomic categories: *Personal Factors:* hometown, age, university year and gender; *Institutional Factors*: secondary school and the specialized area of study or orientation and *Family Factors*: parents' educational background and occupation.

CONCLUSIONS AND IMPLICATIONS

Even though generalizations cannot be made outside the context of this study, it is possible to draw some conclusions regarding the research questions this study sought to answer.

As regards the first two research questions:

In terms of *overall science performance* (OSP); first year students of both university courses obtained low values. In the last years, after instruction, these values increased and especially in Biochemistry.

In reference to *identifying scientific issues* (ISI, focused on aspects of the methodology of science); presented the best results. Biochemistry achieved highest scores in the different stages of study. After instruction, the fifth of Biochemistry achieved further development of this competence than the fifth of Biotechnology.

Explaining phenomena scientifically (EPS, focused on the application of scientific concepts); is probably the most traditional worked competence in the classrooms of science courses as Chemistry. However, it presented the lowest values in the four studied groups. It appears that instruction in Biotechnology develops and increases more this ability, because the last year of this course obtained a higher score.

In connection with, *using scientific evidence* (USE, focused on evidence and argument); both first years have similar values. Subsequently, the results improve with the instruction, though this is the competence in which there are the major differences between the years of study of both courses. It appears that instruction in Biochemistry develops and increases this ability.

Regarding the third research question:

From the analysis we have just made it can be concluded that, in addition to preserving what is already well done, performance could improve if into the instruction would incorporate activities that promote the development of the following:

- To identify relevant scientific questions through tests or scientific procedures.
- To focus on qualitative scientific explanations.
- To work on scientific and symbolic text typology.

As regards the fourth research question:

The results presented can confirm the multicausal character of academic achievement in science, since there are multiple variables that affect them.

In this sense, some links could be established between the results the students obtained in the tests and the personal, institutional and family factors. Without attempting to draw any definite conclusions, it can be identified the following approaches:

- Women get a score slightly higher in science performance than men in the first year and lower in the fifth.
- The educational level of mothers and fathers are factors that are positively related to the results of the tests in science. That is, the conditions of the family environment have an important influence on student performance, although in this study were not absolutely decisive.
- The school obviously affects the acquisition of knowledge. In this sense, the number of hours of science classes and the state schools are issues that contribute to increased student achievement.

All analyzed factors influence students achievement. Coherently with other studies in this area, assert the complexity of the factors associated with performance.

The definition of grades and types of competences can help to diagnose issues that need attention in the analyzed courses. In response to the discovered difficulties, we think of other new lines of work:

- To carry out a longitudinal study into first-year students throughout both courses.
- To design and evaluate educational strategies and teaching proposals that can help students to improve their science competences.
- To study the epistemic levels of arguments, when students answer open questions.
- To validate the test by external methods (cyclical evaluation), that would facilitate the monitoring of the adopted innovations results.
- To search scientific tools to be able to say, as accurately as possible: what is going wrong when the results are low and what is being well done when the test scores improve?

In view of the results obtained in this work, and from the results that could be obtained from the new lines of research that it suggested above, it could consider which profiles are desired for students graduating from Secondary Education, future citizens and future professionals who graduate from the University. In sum, the prospects of education in Latin America (Tuning Project, 2007).

PROBING STUDENTS' UNDERSTANDING OF THE CONCEPT OF ELECTROMOTIVE FORCE IN INTRODUCTORY PHYSICS COURSES AT UNIVERSITY

Jenaro Guisasola[1], Isabel Garzon[2] and Mieke De Cock[3]
[1]University of the Basque Country, Spain
[2]Pedagogic National University, Spain
[3]Katholieke Universiteit Leuven, Belgium

Abstract: This work is part of a research programme on teaching electromagnetism in classical physics. A study on the meaning that future secondary science teachers hold on the concept of electromotive force (emf) within the context of electrical circuits was carried out five years ago. In this work, we will explore in detail how first year university students understand the role played by the emf concept and its meaning in the electromagnetism context within classical physics. The need for information on students' alternative conceptions and forms of reasoning is particularly necessary in areas of the curriculum that have barely been researched due to their type of contents or the level of teaching. To study students' learning difficulties, a questionnaire was designed with three questions within the context of electrical eddy currents in a circuit. The questions are open so that the students have the chance to argue and justify their statements. Students' difficulties seem to be strongly linked to the absence of analysis on variation of the magnetic flux. Most students still do not clearly understand the usefulness of and difference between the concepts of potential difference and emf.

Keyword: learning electromotive force concept, university level, assessment of students' learning.

1. BACKGROUND AND PURPOSE

Measurement of the impacts of traditional teaching in introductory physics is a primary source of data for physics education new proposals. A key question which has been largely investigated in different areas of physics is whether students understand the taught theories and concepts in scientific way. Much work has been done in the past decades in considering the way students approach electrical circuits. Much of this research took place at secondary level. For example, previous studies find that secondary students consider that the current is spent as it passes though a bulb or that the current provided by the battery is independent of the topology of the circuit (Shipstone et al., 1988). Closset (1983) showed that many Secondary and University students analyse the circuit using "sequential" reasoning. This reasoning consists of considering that there is a variable denomination entity, the "current", the "electrons" or the "electricity" with which magnitudes such as intensity or tension are associated. It comes out of the battery and it is more or less affected as it passes through each element of the circuit, for example "the current is used in the resistor" or "the current is spent in the bulb". There is no back dating effect for what might happen to the "current" before the element or after the element; nor does it consider how it returns to the other pole of the battery. Liegeois & Mullet (2002) showed that secondary students have difficulties interpreting resistors connected in series and in parallel in a complete dc circuit.

Duit, Niedderer and Schecker (2008) found three critical areas of deficiencies in students concerning electrical circuits: a) local and sequential reasoning versus global reasoning; b) conceptual understanding of the relationships between current and voltage; c) Ability to apply central relationships in problem solving. Other studies, for example Psillos et al (1988) and Testa et al (2006), are consistent with these general conclusions and found that the concepts of electrical potential and potential difference are frequently confused with the concepts of current intensity or energy, representing the “strength” of a battery. In addition, students frequently do not understand that the potential difference in a circuit depends on its topology. Most of these difficulties seem resistant to traditional teaching of electrical circuits.

Very few studies about assessment of students’ understanding on another concept related to potential difference but with a different physical nature such as the concept of electromotive force (emf) have been made (Varney and Fisher 1980). However, the emf concept is relevant to curriculum of electromagnetism because the following reasons. Firstly, this concept is included in most non compulsory high school programmes (students aged 16-18) and in introductory university physics courses. Secondly, the concept is fundamental to explain the energy balance in direct current circuits and in eddy current circuits. Thirdly, the diversity of contexts where the emf concept is applied makes it necessary to have an appropriate understanding of this concept and to know how to differentiate it from other concepts, related to it but with different meanings such as the concept of potential difference.

In a previous study we have analysed the epistemological context of developing the emf concept and its meaning within the theoretical framework of classical physics (Guisasola et al., 2008). We have found also that High School and University students do not clearly understand the usefulness of concepts of potential difference and emf in the context of dc electric circuit (Guisasola & Montero 2010). In the present study we are interested to determine whether university engineer and physics students who had studied electromagnetism really were able to apply and understand the concept of electromotive force in the context of electromagnetic induction in a circuit. Because this is a collaborative work among three universities from Spain, Belgium and Colombia, we have the opportunity to determine the similarities and differences between students studying physics in these three countries while assessing students understanding on electromotive force.

Spanish, Belgian and Colombian first year physics or engineering students had covered mechanics and electromagnetism subjects during a 2-year period and with a level similar to A level courses in the UK. They also had completed the first semester of scientist or engineering sequence, which focuses on classical mechanic, and had just finished electromagnetism (E&M) program in the second semester. In the three universities the curriculum of E&M is similar to standard programs for introductory physics courses and the used textbooks involves the same sequence of topics (Tipler and Mosca 2004 in Spain and Colombia; Young and Freedman 1996 in Belgium). All students received similar amount of lectures and they have also laboratory. The emf concept is taught by experienced teachers form the physics department in the chapter of dc circuits and in the chapter of electromagnetic induction in a similar amount of hours.

2. RATIONALE

The general theoretical framework for research on alternative conceptions, proposing that prior knowledge and students' conceptions interfere and affect their learning in new contexts, has been used extensively in the literature (Duit and Treagust 1998). However, learning physics and understanding the concepts does not only depend on conceptual understanding but also on the students' ontological and epistemological assumptions that affect the learning processes (Vosniadou, 2002). This research approach is based on the constructivist learning paradigm, which states that both students' prior knowledge and students' conceptions interfere with their learning in new contexts and affect it. This study follows the constructivist epistemology that recognises knowledge of the nature of science as personal and that includes social construction of knowledge to give meaning to observations and natural phenomena (Leach and Scott, 2003).

The need for information on students' alternative conceptions and forms of reasoning is particularly necessary in areas of the curriculum that have barely been researched due to their type of contents or the level of teaching. Although the concept of emf is important, both due to its role as a basic prerequisite for analysing electromagnetic phenomena produced by non conservative fields from an energy point of view, and due to its meaning in technological applications, there is very little research on it in the context of electromagnetism teaching.

3. METHODS

To assess students’ understanding of electromotive force in the context of electromagnetic induction a questionnaire was designed with three questions. The above mentioned approach shares a common form of making a type of questions that require that students don't only merely repeat the theory taught in class but demand the significant application of such knowledge. Therefore, the questions designed place an emphasis on the students’ explanations. Furthermore, the questions are open so that the students have the chance to argue and justify their statements. The questionnaire was given to engineering and physics students from Spain (N=77), Belgium (N=85) and Colombia (N=64), after they had studied the subject in class.

The answers were analysed according to the indications by Miles and Huberman (1994) quoted in Cohen et al. “Research methods in education” (2007). More specifically, three strategies were used: 1) Coding the frequency with which certain ideas or topics appear; 2) Noting down the patterns that can come out of these ideas or causal explanations; 3) Grouping the main items noted down into categories. One member of the research team came up with a draft set of description categories for each question, based on reading the students’ answers. This researcher then reread the students’ answers and tentatively allocated each answer to one of the draft categories. The other researchers carried out this task independently. Once the answers had been classified, answer category allocations were compared. The original categories were redefined until a consensus was reached. Any disagreements about category description or allocations of answers were resolved referring to the answers as the only evidence of students’ understanding. The focus was on the students’ understanding, taking the students’ answer as a whole, rather than focussing on the occurrence of particular statements corresponding to a specific category description. An iterative process was followed to produce final category descriptions that reflected the similarity in understanding among the answers allocated to each category and differences between the categories.

4. RESULTS

The questionnaire was designed in agreement with two of the primary goals in the international standard teaching curriculum for introductory physics courses within the topic of electromotive force. One of the primary goals is that students understand that Electromotive force means the work per unit charge done by non-conservative forces for producing electrical current or for separating charges. The quantity of emf is unique (independent of the physical context) and it measures the work done by non-conservative forces to transfer energy from any energy (Chemical, electro-magnetical) to electrical energy. The second goal is that students understand the difference between electromotive force and potential difference results from measuring different types of action produced by radically different causes. The electrical potential measures the work per unit charge done by coulomb forces. Regarding these teaching goals, in questions Q1 and Q3 students have to discuss the meaning of electromotive force concept in two different contexts (electrical circuits and induced current circuits). The correct answer implies to conclude that the meaning of the concept is the same but the way to calculated it changes depending on the context. The questions were presented as follows:

Q1.- The study of electric and magnetic phenomena considers the electromotive force of a battery and the electromotive force of induction in different chapters. Two students make the following statements:
E1: this refers to the same concept; the only thing that changes is how to calculate it in different contexts.
E2: These are two different concepts. The first considers the electromotive force in direct current circuits and the second considers electromotive force in electromagnetic induction phenomena.

Indicate which of the two students is right and explain carefully why.

Q3. Figure 1 shows a direct current electric circuit with a 12 volt battery as the electromotive force. Figure 2 shows an eddy current circuit that has an electromotive force of 16 volts.

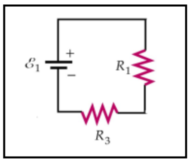

Figure 1

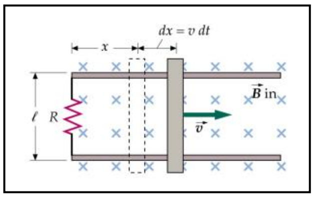

Figure 2

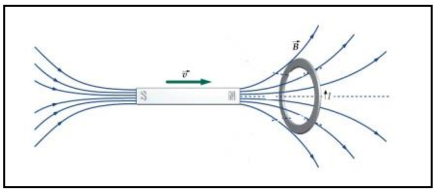
A student states that: "although the two electromotive forces have the same unit, they correspond to two different physical concepts”. Do you agree with the student? Give ***reasons*** for your answer:

The objective of Q2 is related to the second teaching objective. Students have to discuss the difference between the potential difference concept and electromotive force concept based on the work done by conservative and non-conservative charges. The question was presented as follow:

Q2.- When a magnet travels at constant speed closer towards a loop at rest (see diagram), an electric current is induced in the loop. Explain whether the following statement is correct:
"A potential difference has been induced and therefore an electric current appears in the ring."



The results and its categories are showed in the table:

Categories	Q1			Q2			Q3		
	Sp. (77)	Belg (85)	Col. (64)	Sp. (77)	Beg (85)	Col (64)	Sp. (77)	Belg. (85)	Col. (64)
A. Define correctly the meaning of emf	19.5%	7%	19%	8%	7%	8%	20%	3.5%	6%
B. There are two concepts of emf									
B.1. Reasoning based on the "cause" that produces emf	35%	19%	20%	8%	-	8%	37.5%	37.5%	24%
B.2 Reasoning based on the context	23.5%	12%	26.5%	-	-	-	12.5%	10.5%	28%
C. There is confusion between emf and pd	2.5%	15%	6.%	45.%	42%	42%	4%	15.5%	14%
D. 'Ad hoc' arguments are applied with false reasoning or based on poorly memorized data	8%	19%	17%	31%	46%	30%	14.5%	12%	20%
No answer	11.5%	28%	11%	8%	5%	12%	11.5%	21%	8%

There is a minority of answers in category A. Few students focus on the role played by the electromotive force as a magnitude which measures the work per unit charge done by non-conservative forces for reorganising the charges, producing a potential and, in the case of circuits, producing a electrical current. There are variations between the different groups of students but the correct answers are not exceed 20%. In addition, when the question focuses on highlighting the role played by non conservative forces in the definition of emf, the percentage drops and does not rise above 10% (question Q2). When we analyze the answers the criteria is to consider "correct answer" (category A) in a "wide sense" of meaning. Some examples of this category are showed following: "Student E1 is right as the electromotive force is the work per unit charge that is carried out to move the charges. This definition does not change and so the concept of electromotive force is the same as calculated differently in a circuit or in the induction" (Q1, Spain, first year engineering); "Student E1 is correct as the concept of electromotive force is the same. As the emf produced by the battery and the induction emf are produced differently, you have to calculate them differently but the concept is the same" (Q1, Colombia, first year physics). "Correct. In fig 1, the emf comes from the battery and is simply caused by the potential difference. In fig 2, the voltage is caused by the moving bar in a magnetic field" (Q3, Belgium, first year engineering).

Roughly the half of the answers in questions Q1 and Q3 explain that emf concept has two different meanings. In order to justify one concept has two different meanings, the students use two different strategies:

- A justification base on the ‘cause’ (category B.1). The students’ reasoning explain the emf from the effect that is generated in electro-kinetics, whereas the explanation for the induced emf is from the way in which it is generated (the emf is caused). The students’ understanding is interpreted as two different concepts because its “cause or origin” is different. When describing this cause, it is done by an explanation of “how” or of “what”. Two examples explain this category: “It is not the same to talk about electromotive force in a close circuit as in induction. In a closed circuit, the emf is constant and produced by the battery and in the induction, the emf depends on the magnetic flow and the time” (Q1, Colombia, first year physics); “Correct. In the second case, it is about a change in flux in the bar. In case 1, it is about a battery voltage, so chemical energy which is converted to a potential difference” (Q3, Belgium, first year engineering).

- The category B.2 can be considered as a generalization of B.1, in the sense that students’ explanations do not use a causal reasoning for distinguish two meaning of emf, but they differentiate two different emf due to characteristics from the context where it is produced. For example: “Students E2 is correct. The first case is an electromotive force generated by a battery. The second case is an electromotive force generated by an induction phenomeno” (Q1, Spain, first year engineering); “They are two different concepts as one refers to the emf of a circuit and the other refers to a magnetic induction phenomenon” (Q3, Spain, fist year engineering).

- A significant proportion of the answers in this category B (56% in Belgium and 21% in Spain) use concepts of electromotive force, voltage and potential difference as synonyms in their explanations. This can imply that the students do not have their own meaning for each concept and that they do not differentiate them as concepts that measure different physical phenomena. This confusion appears clearly in category C of questions Q1, Q2 and Q3. One example of this type of explanation: “Student 2 is correct. Of course, in both cases, it is about a voltage but a battery always delivers a direct voltage, and direct current and can be computed by $\varepsilon = IR$. An induced voltage is caused by a change in magnetic field/flux. Therefore this voltage is not always constant, because if the magnetic field does not change, there is no ε and the value of ε depends on the change of φ, as $\varepsilon = d\varphi/dt$” (Q3, Belgium, first year engineering)

A half of the answers of the question Q2 explicitly indicates a mix up between emf and potential difference (category C). For example: “Upon introducing emf, a variable potential difference is induced in the ring” (Q2, Colombia, first year physics); “Yes, it is correct. As the magnet moves closer to the coil, it produces a current and therefore difference in potential” (Q2, Spain, first year engineering); “This is true. As the magnet moves closer, the field lines passing through the coil increase and an electric current is induced, meaning a potential difference. $\Delta V = I\,R$” (Q2, Spain, fist year engineering).

5. CONCLUSIONS

Students’ difficulties seem to be strongly linked to the absence of analysis on the work carried out by conservative and non-conservative forces on the phenomena and its energy balance. Concurring with results from other investigations (see background) and our previous results, it can be interpreted that when the context is within electrical circuits, the majority of the students are not clear on what emf is, and therefore the battery is talked of as a generator of emf, much like a “black box”. For that same reason, they do not talk of transforming chemical energy into electric, nor the non-conservative field …etc. On the other hand, in the context of induction, the stress is on the cause that generates emf (variation of magnetic flow in time) describing how it is generated. From this perspective, as the majority of the students have the “causes” that produce the emf as different, the concepts are also different.

Most students still do not clearly understand the usefulness of and difference between the concepts of potential difference and emf, not in situations involving direct current circuits and not in eddy current circuits.

In all cases, we found evidence that Students’ difficulties are strongly linked to the lack of meaning of emf. The results of the study show that teaching will be explicitly points out some conceptual key aspects of the electromotive force such as: a) electromotive force is related to work made for moving charges; b)The magnitude of emf is unique and it measures the work done to transfer energy from any form (Chemical, electro-magnetical) to electrical energy; c) it will be necessary to justify that the difference between electromotive force and potential difference results from measuring different types of action produced by radically different causes. Consistent with a constructivist approach of teaching and learning, which take into account students’ conceptions, teachers would not only teach based on straightforward transfer of concepts and laws with illustrations of ‘ad hoc’ examples; it will be necessary to design learning sequences that do not just explain the key ideas already mentioned but which also use a teaching strategy which gives students the opportunity to use scientific procedures such as putting forward hypothesis about the relevance of a model for the problem proposed, suggesting a number of different strategies to explain it and justifying the answer based on evidence.

STANDARDIZATION IN PHYSICS – FIRST STEPS IN THE AUSTRIAN EDUCATIONAL SYSTEM

C. Haagen[1] *and M. Hopf*[1]
[1]University of Vienna, Austrian Education Competence Centre Physics, Austria

Abstract: The definition of standards and the development of competence models in science education has been one major endeavor in several European countries during the last decade. Like in many other countries, this issue was also brought up in Austria, due to low results in international student assessments (PISA, TIMMS). In 2007, a project group was installed by the Ministry of Education to implement national educational standards for science (grade 8). The objectives for the implementation phase (2007-2011) were the development of a competence model for science and of a pool of archetypal tasks to exemplify and evaluate the model. In a series of 5 pilots (N_{min}=3597; N_{max}=8559) archetypal tasks were assessed in form of a paper & pencil test (1st pilot) and online tests (pilots 2-5). Up to now, a normative competence model for the subjects biology, chemistry and physics was developed and operationalized in 70 archetypal tasks. Interim results suggest that those tasks so far developed, cover a wide range of the competence model. Additionally, there are hints that they indicate competence (in Weinert's (2002) concept of competence) rather than content knowledge.

Keywords: Standardization, Competence, Physics, Archetypal Tasks

1. INTRODUCTION

The definition of standards and the development of competence models in science education has been one major endeavor in several European countries during the last decade (Waddington *et al.* 2007). This issue was also brought up in Austria due to moderate or even low results in large scale student assessments like PISA, or TIMS. One strategy of reaction was to develop and implement educational standards to change the focus of the educational system from input-orientation to output orientation.

In general, standards specify students' competences at a certain grade and describe the expected learning results. Focus is put on the basic concepts of a subject. In Austria it was agreed upon performance standards handled as regular standards, which are supposed to describe a regular level of demands.

Normative competency models, based on Weinert's concept of competences (Weinert 2002), should serve as a starting point for the process of standardization in Austria. According to Klieme et al (2003), normative competence models have a kind of bridging function between the abstract goals of education and the concrete problems students are expected to solve.

As second theoretical basis served the concept of scientific literacy as used in 2004's Learning for tomorrow's world: "The emphasis of the PISA 2003 assessment of science is on the application of science knowledge and skills in real-life situations, as opposed to testing particular curricula components. Scientific literacy is defined as the capacity to use scientific knowledge, to identify questions and to draw evidence-based conclusions in order to understand and help make decisions about the natural world and the changes made to it through human activity.“(Programme for International Student Assessment, 2004)

2. IMPLEMENTATION PROCESS OF SCIENCE STANDARDS IN AUSTRIA

In 2004, the Ministry Education initiated the implantation process for educational standards for the core subjects in grade 4 (German, mathematics) and in grade 8 (German, mathematics, English) (Lucyshyn 2004). In 2005, a start was made to develop standards for science subjects for the vocational school system in grade 12 and in 2007 for the lower secondary level in grade 8. In the following, working groups for all subjects, consisting of experienced teachers, educational researchers and representatives of the Ministry, were appointed to develop competence models.

Einhaus and Schecker (2007) have suggested the following 3 stages for the development of a competence model for national educational standards:

(1) development of a normative competence model as basis for further research
(2) development and validation of a suitable test instrument for the competence model
(3) verification of the normative competence model and adaption according to the structure of students’ abilities by empirical data.

Austrian policy makers, however, decided that the development of the competence model for science should not be directly succeeded by the construction of psychometric tests. Instead, the project group were to construct and assess archetypal tasks (Labudde et al. 2009) after developing a normative competence model for science.

The implementation process of science standards grade 8 in Austria was also planned in three main phases. Some differences to the procedure suggested by Einhaus and Schecker (2007) can however be noted: As in many other countries the first step was to develop a normative competence model for science subjects 2007 (Weiglhofer 2007).

The second step differed form common procedures of standardization. The emphasis was not put on a psychometrical valid test instrument, but rather on the development and evaluation of so called “archetypal tasks” in a series of 5 pilots between 2008 and 2011. The creation of archetypal tasks aimed at two different goals. One was to exemplify the dimensions of the competence model to teachers, since archetypal tasks are instructional assignments rather than test items. So awareness should be created for instruction focusing on competences instead on mere content knowledge. The second aim was to improve the competence model for science subjects itself based on the empirical data collected by piloting archetypal tasks.

Finally, a third step was planned for the development and validation of psychometric test items and nationwide baseline tests. The schedule for phase 3, however, is still open.

3. RESEARCH QUESTIONS & METHODS

The standardization project contained a huge number of research questions. The main research questions discussed in this contribution focus on two different target groups, students and teachers. Research questions on the level of students were:

- To what extent are students able to solve archetypal tasks?

- How do students rate the degree of difficulty of archetypal tasks?
- Is there a difference in performance between schooltypes?
- How motivated are students to do individual archetypal tasks?

On the level of teachers we were interested in the following questions:

- To which extent do teachers use similar tasks in their lessons?
- How do teachers evaluate the classification of the archetypal tasks within the normative competence model?

In a series of 5 pilots (2007-2011) a pool of PISA-like problems (archetypal tasks) based on the dimensions of the competence model was assessed. In each pilot phase tasks of each subject (biology, chemistry, physics) were grouped together into different task booklets. Besides these tasks, questionnaires for accompanying research were used. Students of adequate grade 8 samples worked on one booklet each. While the first pilot was administered in the form of a paper and pencil test, the following 4 pilots were assessed online.

The research process started in May 2008 with a nationwide assessment (N>6993) of one task booklet per subject (10 problems in total) in form of a paper and pencil test. In February 2009, 6313 students worked on three task booklets (10 problems in total, 1 booklet per subject).

In September 2009 the core project team was enlarged to 10 members for each subject. Based on the results of the first two pilots, archetypal tasks were refined and new ones were developed. In February 2010, in pilot three, 8559 students took part in the online assessment of in total 23 tasks, in 3 booklets for each subject and in June 2010, 3597 students worked again online on 27 tasks. The series of pilots was to be concluded in February 2011. Additionally, experimental tasks will be assessed by small samples.

4. RESULTS

The Austrian competence model for science year 8 was based on international models (eg. National Research Council, 1996; CMEC 1997; Bybee 2002; KMK, 2005). The resulting three-dimensional competence model is combined for the subjects biology, chemistry and physics (Weiglhofer 2007). It includes competences of acting (1st axis), three levels of complexity (2nd axis) and domains of contents (3rd axis), which are specified for each science subject separately. The spectrum of competences of acting consists of three main components: 1) observing & describing 2) investigating & interpreting 3) assessing & judging. For physics, five domains of content were chosen: mechanics, electricity & magnetism, heat, optics and properties of matter.

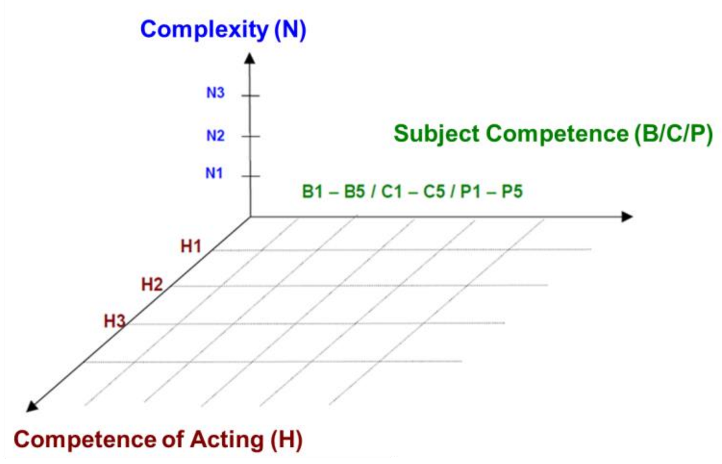

Figure 1: Austrian Competence Model

The archetypal tasks mentioned earlier represent knots in the competency model. The descriptors of these three dimensions are work in progress, they are fine-tuned with data collected in the pilots.

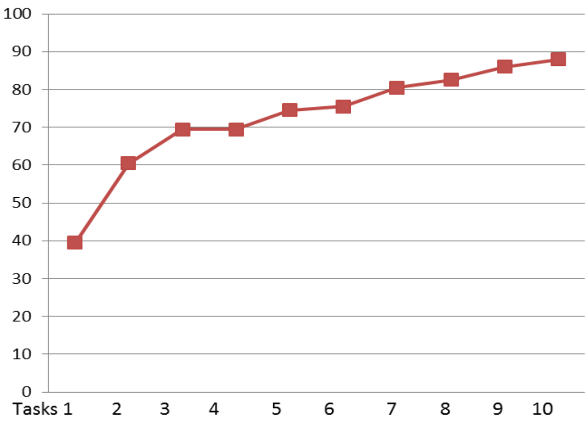

Figure 2: Solution Frequency in percent

In this contribution empirical data collected in the February 2010 pilot is presented. Solution frequencies of the tasks varied between 39,5% and 88,0%. Students assessed the difficulty of the physics tasks on a scale from 1 (=very difficult) to 5 (=very easy) as medium (M_{FEB}=3,01). Further findings are performance differences between students from grammar school and secondary modern school. Students from grammar school (Gymnasium) perform significantly better than students from secondary modern school (Hauptschule) on the basis of $p<0.05$. Students of secondary modern school regard tasks significantly more difficult than students from the natural science track of grammar school.

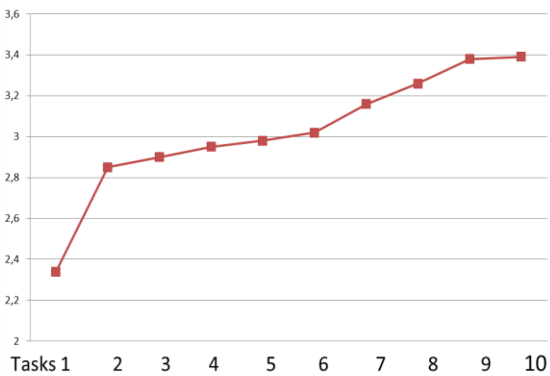

Figure 3: Difficulty assessed by students (1=very difficult, 5=very easy)

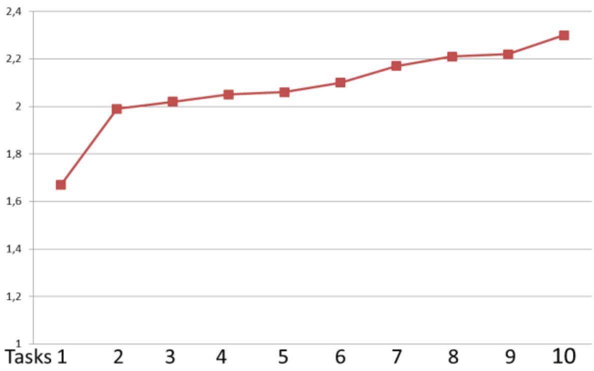

Figure 4: Students' motivation (1=low motivation; 5= high motivation=

The results of the teacher questionaires indicate that teachers hardy use tasks identical with the archetypal task for instruction. In most cases, the majority of teachers agree with the classification of archetypal tasks within the normative competence model.

5. Conclusions and Implications

In general, the research project science standards grade 8 has contributed to the discussion and definition of competences in science instruction and resulted in a normative competence model. The development and piloting of archetypal tasks set first steps in the evaluation of the competence model and served as opportunity to promote the idea of science standards among teachers. An additional benefit is the freely accessible pool of examples of good practice (archetypal tasks) for instruction and learning which can also be used as a diagnostic tool for individual student evaluation.

As far as the evaluation of the archetypal tasks is concerned, the range of the average solution indicates that a wide spectrum of competences defined in the competence model has been covered so far. Although the content of the tasks is in the majority of cases familiar to the students, students' achievement is for most tasks not correlated to their familiarity with the content. This may be seen as a first indicator that the archetypal tasks indicate students' cognitive abilities and skills to handle particular problems (Weinert 2002, p.27f) rather than their mere content knowledge.

MEASURING EFFECTS OF NON CONVENTIONAL LABWORK

Martin Hopf [1]
[1]University of Vienna, Austrian Education Competence Centre Physics

Abstract: Laboratory learning environments are often criticized as not being effective. Research has only shown controversial effects of laboratory learning environments on students' learning, attitudes etc. Based on the criticisms a problem based, guided inquiry laboratory learning environment was developed to foster students' conceptual understanding. To assess the effects of this learning environment, a comparative study with a Pre-Post-Follow-Up-Design was carried out with N = 320 students from grade 9 and 10. Among the instruments used were knowledge tests, surveys on interest and self concept as well as an adapted version of SLEI. To study the processes during labwork, a smaller sample of lessons were videotaped and analysed with CBAV categories.
While the analysis showed, that students from EG outperformed CG by time spent on working on the experiments and discussing physics concepts, the summative measurements found no major effects of the intervention, neither for conceptual understanding nor for interest or self concept. Also the perception of the laboratory environment by students did not differ between the groups. The presentation will focus on the consequences of these results for measuring effects of non conventional laboratory learning environments.

Keywords: Laboratory learning; experimental competence; Assessment; Problem-Based Learning

INTRODUCTION

There are a lot of goals for the science laboratory. Most prominent among them is that students can get a better understanding of the science concepts by doing experiments. However the effectiveness of learning in laboratories has been criticized over many years. One of the most cited criticisms is that students are not fully engaged in thinking about their lab work while doing it. Instead they follow a list of tasks in a "cookbook"-style laboratory guide (Hofstein & Lunetta, 2004). Hence they miss the chance to get a better understanding. This may account for the negative results of empirical research on learning in the science laboratory. Most findings do not support that students working with experimental materials grasp science better (Singer, Hilton & Schweingruber, 2006). In a socio-constructivist view of teaching and learning, to enhance students' performance, these criticisms have to be changed to guide students towards active learning in the laboratory.
For this reason, a learning environment for the physics laboratory was developed, which takes into account the criticism of the literature. Adapting an idea from van Heuvelen (1995) a problem-based, guided inquiry approach was developed. Therefore a typical experiment from a grade 9 (introductory optics) respectively a grade 10 (introductory electricity) laboratory was reformulated into an "ill-defined" problem. E.g. instead of finding the right additional resistance for a voltmeter, the problem stated was to

measure an unknown voltage with an antique instrument without damaging it (fig. 1).

Figure 1: Get this phone (built for 3.8V) running with a 9V-battery. It will break, if you use higher voltage!

All of the problems were constructed in a way, that trial-and-error-strategies were not successful to solve the problem. To find a solution, students had to understand the problem, find out what experiments to perform and which concepts to use explaining their experimental findings. To foster students' interest in this kind of laboratory work, the problems furthermore were constructed in interesting contexts. In this way, a nonstandard laboratory learning environment (PBLL) was built.

To evaluate the effects of this learning environment, the following hypotheses were chosen:

(1) Students working with PBLL spend more time on the task and talk more about physics.
(2) Students' perception of PBLL is better than of traditional laboratory work.
(3) Students' conceptual understanding is promoted by PBLL.
(4) Students' interest is promoted by PBLL.

METHODS

To find answers, a comparative empirical study in 9^{th} and 10^{th}-grade classrooms was planned and carried out. In grade 9 (optics), 4 classes (n = 70) worked with PBLL at an average of 8 lessons, 2 classes (n = 55) worked with traditional laboratory guides for the same time. In grade 10 (electricity), 7 treatment classes (n = 184) worked with PBLL, 4 control classes (n = 101) did traditional labwork. The length of the intervention was 10 lessons. In Bavaria where the study was carried out, traditional labwork means the use of cookbook-style, laboratory guides (TL).

In all groups, questionnaires and knowledge tests were given as pre- and post-tests. In a smaller sample also a follow-up test was administered. Although a nonstandard learning environment was to be tested, a unbiased test could only be made using instruments proved valid in the literature for standard laboratory settings.

The questionnaire consisted of adapted and translated subscales of SLEI (Fraser, Giddings & McRobbie, 1995) and a subscale of CLES on personal relevance (Taylor, Fraser & Fisher, 1997) to measure students' perception of the learning environments. To track the development of students' interest, a instrument by Berger (2000) was adapted and administered. Students' conceptual understanding was measured with knowledge tests. These knowledge tests consisted of standard items (Herdt, 1990; Rhöneck, 2004), additionally selft-constructed items were used.

To document the process–of students' laboratory work, a small sample of students were videotaped. These videos were analysed in 10-second loops with an adapted version of the CBAV-category system (Niedderer, Tiberghien, Buty, Haller, Hucke, Sander, Fischer, Schecker, Aufschnaiter & Welzel, 1998). Furthermore, semi-structured interviews with students and teachers were held and field notes were taken.

RESULTS

The results of the empirical study are quite heterogeneous. The data from interviews as well as the analysis of the field notes showed that the developed material worked well in the classroom. All of the interviewed teachers and students liked PBLL and required the development of more learning environments like this. The field notes showed that all students had problems on their first encounter but soon got acquainted with the new approach and worked intensively.

These results are supported by the analysis of the video tapes. CBAV-Categories showed that in PBLL, students spent significantly more time on working with the experiment (fig. 2) and discussing physics respectively physical connotations of the experiment (fig. 3). These effects originated mainly from underachieving students. For high achieving students, video analysis from PBLL and TL did not show differences, neither in students' verbalisations nor their activities.

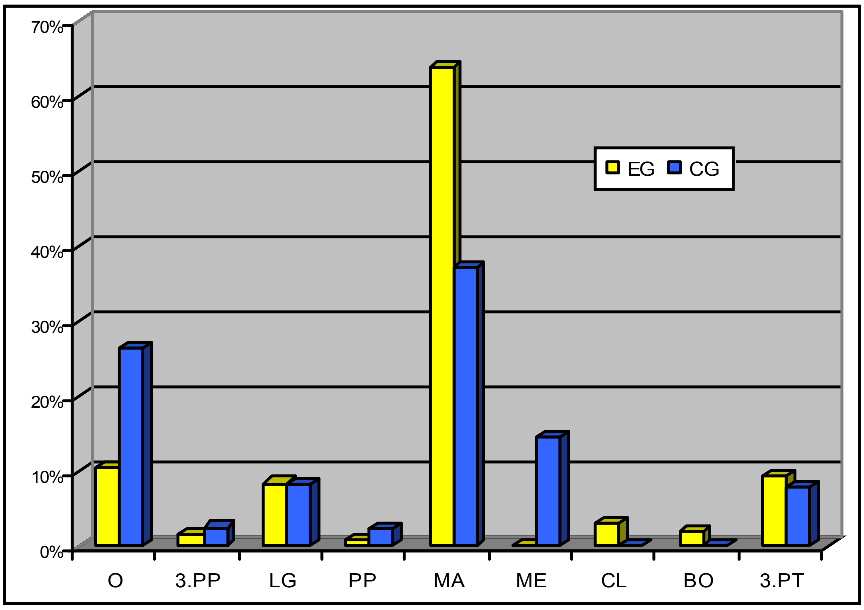

Figure 2: Students' activities (O: Other; 3.PT: Interaction with tutor; 3.PP: Interaction with peer; LG: Reading of lab guide; PP: Paper & pencil; MA: Manipulation of apparatus; ME: Measuring; CL: Calculation; BO: Using textbook)

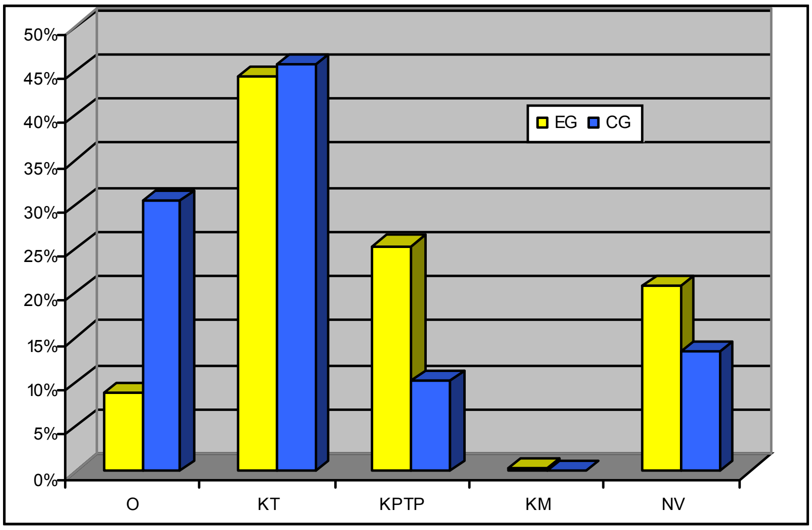

Figure 3: Students' verbal (O: Other; KT: Technical aspects; KPTP: Technical and physics aspects; KM: Mathematics; NV: No verbalizations)

A problem arose with the questionnaire. Only one out of the three used SLEI-scales could be replicated in the sample (student cohesiveness, $\alpha = 0.811$). Comparing pre, post and follow-up-tests, only minor differences between EG and CG could be found. Although all effects are in favour of PBLL, no significance could be detected. For both of the scales Open-Endedness and Integration of SLEI, Cohen's alpha yielded insufficient values. The scales 'Rule Clarity' and 'Material Environment' gave the impression not to fit the research questions and were not used in the study.

The scale 'personal relevance' from CLES could be replicated ($\alpha = 0.885$), but also in this scale only small effects for TG over the period of the study could be found.
On the two scales of interest (global interest for physics classes, $\alpha = 0.821$ and actual interest for doing experiments, $\alpha = 0,791$), small effects ($d = 0.1$ – $d = 0.3$) could be seen. Most interesting was that these effects are all due to a decrease of the CG values, not due to an increase in EG.
The results of the knowledge tests were heterogeneous. Whereas in 10th grade the TG outperformed CG slightly ($d = 0.25$; fig. 4), in 9th grade this happens the other way round ($d = -0.26$; fig. 5).

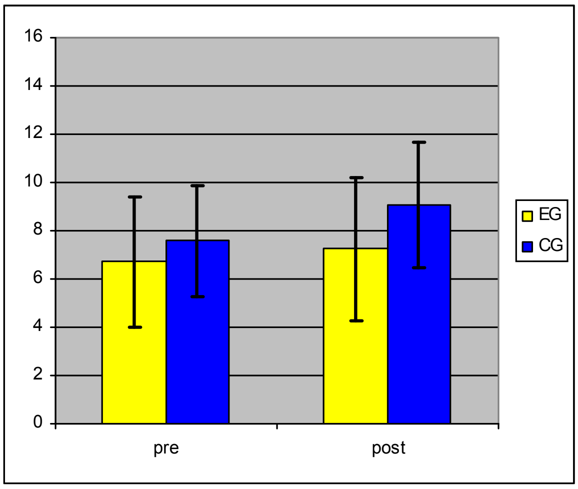

Figure 5: Understanding in Optics, 9th grade, max. 16 pt

CONCLUSIONS AND IMPLICATIONS

The conclusions from these results are ambivalent and several valid interpretations can be found. There are contradictory effects: on the one hand, with PBLL students work as planned. They experiment with the given materials, the time is much more on-task than in TL. Students talk about physics and its relation to their experimental data. On the other hand this has no sizeable effect on interest for experiments, on interest for physics lessons and on the perception of the laboratory environment. Furthermore – taken both grade levels into account – no effects on students' learning due to PBLL. Thus an old result of empirical studies on learning in the laboratory was replicated: The use of experiments per se does not lead to a better understanding of physics. But also a learning environment which takes all criticisms into account, does not lead to a better understanding of physics or to better student attitudes.

In my opinion learning physics is not directly influenced by the way the laboratory is constructed.
Another interpretation could be: The main aspect of the effectiveness of laboratory learning is its inclusion into the curriculum. For the reported empirical study, this was not the case. To assess the effects of PBLL versus TL it was decided, not to include the treatments directly into a physics course. But it was agreed to add it to regular physics classes. This may be a major point of critic against the results; in a replication of the study, this should be taken into account.
At last a third interpretation can be made: What happened in the PBLL resp. TL laboratories could not be measured by the reported instruments. Learning processes in the laboratory are much more complicated than to assess them with traditional knowledge tests or interest questionnaires. But the aim of the reported study was to evaluate the effects of PBLL exactly in these measures. A result is therefore, that there are no effects of different types of laboratory learning environments measured by paper-and-pencil-tests.

DEVELOPMENT OF SCALE FOR ATTITUDE TOWARDS PHYSICS COURSE

Gokhan ILGAZ[1] *and O. Tolga ARICAK*[2]
[1] Trakya University, Turkey
[2] Fatih University, Turkey

Abstract: The purpose of this study was to develop Likert type scale for measuring attitudes towards physics course while examining construct validity and testing the fit between independence model and the hypothesized model through confirmatory factor analysis (CFA) after performing exploratory factor analysis (EFA). Research's dates were collected seven high schools students in Center city in Edirne, 2006-2007 academic year, and spring term. Missing dates were taken part in data analysis. The Scale for Attitude Towards Physics Course (SATPC) was administered 865 students who 492 girl, 373 male. Students' age ranges change from 14 to 18 (M=15.78, SD =.82). It was considered that the scale of measuring attitude towards physics course had unidimension construct as the result of EFA and CFA was performed to analyze validation of theoretical construct for further analyses. Results show that the scale had unidimension construct. Accordingly, internal consistency reliability analysis and test-retest were performed. Cronbach alpha was .95 which indicates a high internal consistency. According to test-retest's results, the both measurements are significantly correlated with each other in high level (r=.76, p<.05). Finally, psychometric results of "SATPC" showed that the scale had construct validity and reliability.

Keywords: Physics Course, attitude, high school students, confirmatory factor analysis

INTRODUCTION

Researches suggest that there is a positive correlation between attitude toward science and science achievement (Mattern & Schau, 2002; George & Kaplan, 1998). According to Osborne, Simon and Collins (2003, p. 1053), attitudes towards science, "are the feelings, beliefs and values held about an object that may be the enterprise of science, school science, the impact of science on society or scientists themselves." There are four pillars of science education. These are "attitudes towards: (a) the science subject itself as a discipline; (b) the learning of the science subject; (c) topics and themes covered in a particular course (e.g., themes of social awareness); and (d) the methods of science (the so-called scientific attitude). Although much of the disseminated research has focused on the first target (Reid, 2006, p. 7), much of the work on attitudes has concentrated on attitudes towards the specific science area (usually physics, sometimes chemistry)" (Reid, 2006, p. 8).

As known, science consists of physics, chemistry and biology, and these disciplines function independently. Thus investigating attitudes towards physics, chemistry and biology independently is better than taking the general attitude toward science alone because students have different attributions towards these scientific disciplines. This will provide further information about students' attitudes towards science (Şengören, Tanel & Kavcar, 2007).

Many countries face significant problems with engaging students with the advanced study of physical sciences (Osborne & Dillon, 2008, p.13). Whereas many topics can be integrated to physics education (Juuti, Lavonen, Uitto, Byman & Meisalo, 2003, p.57) within the science, physics is considered as the most problematic area and it traditionally attracts fewer pupils than chemistry and biology (Reid & Skryabina, 2002, p. 67). According to Williams and his colleagues (2003, p.324), the major general reasons for finding physics uninteresting are that it is seen as difficult and irrelevant. And also because of the changing nature of physics over the secondary school period, physics becomes increasingly difficult, less descriptive and more mathematical (Owen, Dickson, Stanisstreet & Boyes, 2008). Literature addresses that the perception of a person as being difficult tends to result in the development of a general negative attitude to that subject (Williams et al, 2003, p.329), and this negative attitude may cause low achievement. This needs more additional research on attitudes toward physics.

To find reliable results without error, the researches and teachers have to use valid and reliable scales. When we look at literature, we can find many scales which measure "attitude towards science", but we can't find "attitude towards physics course" which is valid and reliable because it is not widespread. In Turkey, in some researches, we can see "scales of attitude towards physics/ physics course" adapted from other scales which were developed by another course or subject or by combining items of many other scales. In the literature we recognize that the informations about the details of scales are not articulated in many studies, instead well-known scales related to subject searched are preferred for quick use (Kurnaz & Yiğit, 2010, p. 35).

RATIONALE

The purpose of this study was to develop Likert type scale for measuring attitudes towards physics course while examining construct validity and testing the fit between independence model and the hypothesized model through confirmatory factor analysis (CFA) after performing exploratory factory analysis (EFA).

METHODS

Data were collected from seven high schools in Edirne in Spring of 2006-2007 academic year. The SATPC was administered 865 students (492 girls, 373 males). Students' age range changes between 14 and 18 (M=15.78, SD =.82). Authors of the current study aimed to develop three different scales for biology, chemistry, and physics courses. Although each study was conducted in parallel way, authors developed three different scales using different samples. In the current study, researchers examined literature to identify variables which was included by attitude. Then researchers wanted 20 high school students in tenth grade write a composition about their feelings and thoughts on physics course in March 2005. Content analysis was performed for these compositions. In terms of literature and content analysis, researchers produced 46-item for SATPC. After re-examining process, number of items was reduced 23 because some items could be confusing.

EFA, Cronbach α, Pearson correlation and independent sample t-test were performed in SPSS 17 for Windows. CFA was performed in AMOS 16.0. "Maksimum likelihood (ML)" method was used for both EFA and CFA (Tabachnick & Fidell, 1996, s.665; Brown, 2006, s. 49).

RESULTS

The EFA (with ML and direct oblimin rotation with delta set at 0) was conducted. The Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy was .968, which suggested that data were appropriate for factor analysis. In addition, Bartlett's test of sphericity was found to be statistically significant, $\chi^2(231)=12072.794$ $p<.05$. This finding also indicated that the sample was suitable for factor analysis.

While deciding on the number of factors, the eigenvalues greater than one and the scree plot were used as criteria. In additon .32 was used as a critical value to examine factor pattern loadings (Tabachnick & Fidell, 1996). According to result of first EFA, although the eigenvalue was greater than one suggested remaining three factors, scree plot and factor matrix yielded one-factor model. The item 8 was removed because it didn't take place in first factor and the EFA was again conducted. As a result of second EFA, SATPC revealed one-factor and this factor explained 49.56% of total variance.

CFA was performed to test a one-factor model of the SATPC (see Figure 1). While evaluating goodness of fit, RMSEA (the Root Mean Square Error of Approximation), TLI (Tucker-Lewis Index) and CFI (Comparative Fit Index) were used as critical values. (Tabachnick & Fidell, 1996; Brown, 2006; Weston & Gore, 2006). Results demonstrated a satisfactory fit for model (RMSEA=.075 TLI=.892 CFI=.911). According to Browne and Cudeck (1993) values of RMSEA between .05 and .08 indicate modarate fit. Accoding to Brown (2006), TLI and CFI values should be 0.90 and higher. The standardized regression coefficients of the one-factor SATPC changed from .43 to .88 and all of these coefficients were statistically significant.

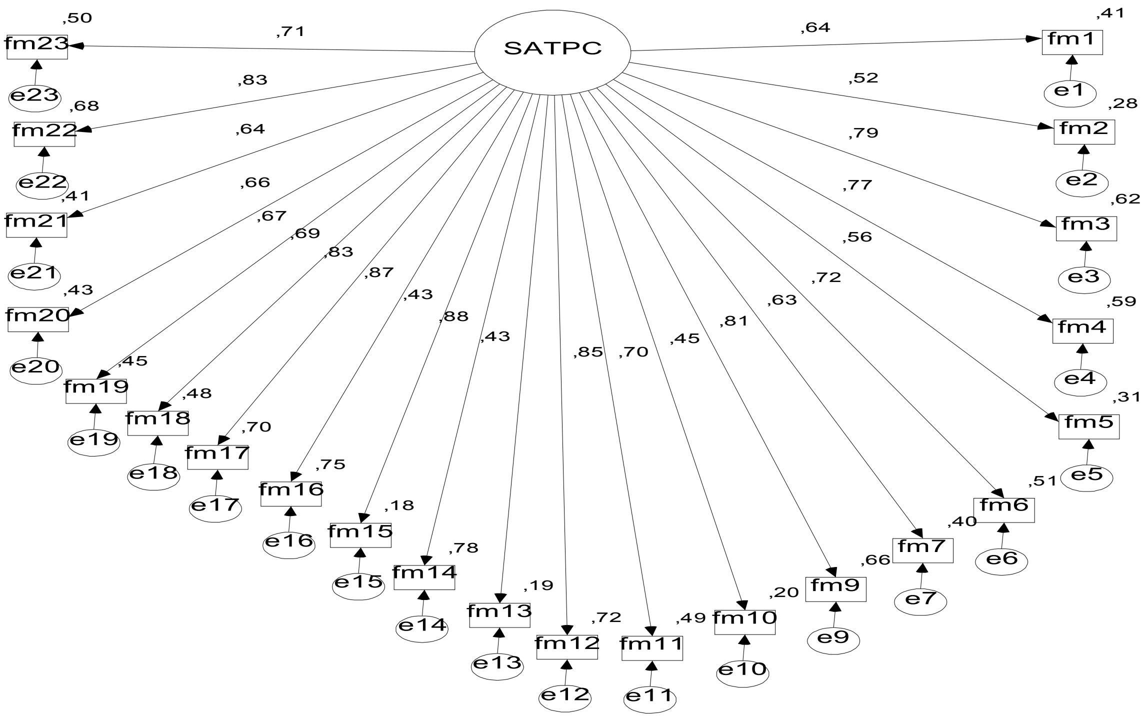

Figure 1. CFA of SATPC

The correlations of items consisting of the whole total scale were calculated in order to determine whether each item included in the scale is related to the concept which was wanted to worked out. Afterwards, in order to determine to what extend adequateness of each item included in the scale in distinguishing the individuals in terms of the feature which they evaluate for the meaningfulness of difference between item points of the top 27% and the bottom %27 groups which was determined by total point, t-test was used.

Tablo 1. t test for %27 low and high groups and item total correlation

Item	t (%27 low and high groups)	Item-Total Correlation	Item	t (%27 low and high groups)	Item-Total Correlation
fm1	22.40*	.62**	fm13	13.78	.44**
fm2	15.76*	.53**	fm14	38.09	.86**
fm3	29.46*	.78**	fm15	12.34	.45**
fm4	28.84*	.74**	fm16	38.02	.84**
fm5	18.28*	.57**	fm17	37.12	.81**
fm6	22.84*	.71**	fm18	29.81	.68**
fm7	21.84*	.61**	fm19	23.47	.66**
fm9	34.82*	.80**	fm20	21.65	.65**
fm10	13.14*	.46**	fm21	18.44	.61**
fm11	22.54*	.69**	fm22	33.80	.81**
fm12	36.40*	.82**	fm23	24.94	.70**

*p<.05 (t test), **p<.05 (correlations)

According to the Table 1, item total correlation is meaningful and it changes between .44 and .86. In addition to this, it can be considered that the items have discrimination power according to t test results.

Furthermore, whether there is difference among attitude points of the students or not is tested according to willingness of the students towards physics subjects. It was seen that attitude points of the students having high level willingness towards physics course ($\overline{X}_{high}$=79.357) are significantly higher than the students having low level willingness ($\overline{X}_{low}$=53.733) [$t_{(815)}$=23.38, p<.05]. This finding suggested that the discrimination power of the scale exists.

The Cronbach alpha coefficient was .95. The scale was administered to the same group (n=105) two times in four weeks interval to determine the test-retest reliability of the scale. Correlation coefficient was found as .76 (p<.05).

CONCLUSIONS AND IMPLICATIONS

The purpose of the current study was to develop SATPC. According to EFA, the scale consists of one-factor, and this structure was validated by CFA. In additon, it is known that there is a relation between the construct validity and internal consistency. The Cronbach alpha coefficient was high and deemed acceptable. Further validation with different populations and cultures would also warrant increasing external validity.

SECOND LEVEL IRISH PUPILS' AND TEACHERS' VIEW OF DIFFICULTIES IN ORGANIC CHEMISTRY

Anne O' Dwyer[1] *and Peter Childs.*
[1]University of Limerick, Ireland.

Abstract: Chemistry has been identified as a difficult subject by many and a decrease in the numbers studying Chemistry has been found in many countries (Reid, 2008). Childs & Sheehan (2009) have identified the Organic component of Chemistry as a problem area at second and third level in Ireland. This investigation was conducted as part of a research study looking at the difficulties of Organic Chemistry for second and third level students in Ireland. Chemistry Teacher Questionnaires were distributed to 73 participating schools and Second Level Pupil Questionnaires were distributed to 35 participating schools in Ireland. The Chemistry Teacher Questionnaire investigated the teachers' perceptions of teaching Organic Chemistry. The Second Level Pupil Questionnaire sought background contained a Diagnostic Test assessing nine core Organic Chemistry topics. The average score on the Diagnostic Test was 53 %. The main areas of difficulty identified by teachers and pupils in this study were: Structural Formulae, Functional Groups, Characteristics of Organic Compounds, Organic Reactions (types and mechanisms) and Laboratory Work.

Keywords: Organic Chemistry, chemical misconceptions; conceptual understanding

BACKGROUND

Many researchers have recognised a mismatch between the enthusiasm of Chemistry lecturers and teachers and their students' interest levels (Johnstone 1991, Johnstone 2010, Johnstone and El-Banna 1986, Millar 1991). Johnstone (2010) has recognised a snowball effect of recurring misconceptions in Chemistry education at second and third level over the past 40 years. Too much attention has been given to the 'chemical', and not enough attention given to the 'education' part of 'Chemical Education' (Ellis 1994, Mahaffy 2005). Many people have highlighted the gap in communication between those who carry out Chemical Education Research (CER) and those who teach Chemistry (Ellis 1994; Childs 2009). In addition many research studies involve sample groups of high-ability learners, so the findings may not be generally applicable. Many revised curricula and associated textbooks are still failing to understand how young people learn.

> "*We have been busy changing the menu in the ship's restaurant while the ship had been sinking"* (Johnstone 2010, p.22)

Rather than developing new curricula and programmes for teaching Chemistry, it is more important for chemical educators to first understand the processes of learning. Johnstone listed nine areas of Chemistry that were established as difficult in 1971. Many of these same topics were again identified as difficult by Ratcliffe (2002), Jimoh (2005), Johnstone (2006) and in Ireland by Childs and Sheehan (2009). These studies indicate that there is a persistent problem with how Chemistry is being taught and highlights the urgent need for change. Much of the CER focus seems to be on the "classic core" Chemistry topics of the mole concept, the particulate nature of matter, equilibrium, and chemical calculations. While extensive reseach has also been carried out in investigating learners' difficulties with Organic Chemistry very little has been done in this area in Ireland.

REVIEW OF LITERATURE

Organic Chemistry is an essential part of everyday life; it has enormous economic significance, particularly in Ireland with its sizable pharmaceutical industry and is major part of the Irish Chemistry syllabus. However, for those learning Organic Chemistry for the first time, it can

cause confusion and difficulty. There are three main difficulties in Organic Chemistry (Ellis 1994): there are no problem-solving algorithms; it requires three-dimensional thinking; and it has an extensive new vocabulary. As a subject it has a difficult reputation, as students do not see its vitality and relevance in the typical second level or third level course.
"*Among students, the organic chemistry course has a bad reputation of mythic proportions. From their viewpoint organic chemistry is a dreaded 'wash-out' course*"

(Katz, 1996, p.440)

The abstract concepts of Chemistry require thinking on several levels, and Organic Chemistry is no exception to this. Johnstone (1991) described the multi-level thought needed in Chemistry in his 'Triangle of Chemistry'. The learner is faced with three levels of thought: the macroscopic, submicroscopic and symbolic. The 'Macroscopic' level refers to what is tangible and visible e.g. a salt dissolving in water. The 'Sub-microscopic' level refers to what is molecular and invisible e.g. the sodium and chloride ions and water molecules. The 'Symbolic' refers to the chemical symbols and equations to represent the ions and atoms and molecules etc. e.g. $Na^{+}_{(aq)}$ and $Cl^{-}_{(aq)}$. While an expert may be able to move easily between these levels, the combination of just any two levels, or even the comprehension of the non-macroscopic levels, can be demanding for a beginner. Much research (Johnstone 1981, Childs and Sheehan 2009, Ratcliffe 2002, Johnstone 2006) over the past 40 years, has found Organic Chemistry to be one of the main areas of difficulty for pupils at second level.

Piaget's model of Cognitive Development suggests that the cognitive ability and development of the learner is age-dependent. Reaching the formal operational stage of development at 11 years, as Piaget first suggested, should mean that these learners can then handle abstract ideas and think logically. More recent research has shown Piaget's ages to be too optimistic. Work carried out by Shayer and Adey (1981) in the UK and again in 2007 (Shayer et al. 2007) showed that the percentage of pupils at age 16 reaching the formal operational level was much lower than previously thought. This work has been repeated recently on Irish pupils and students, and showed that less than 20% of pupils at senior cycle in second level and less than 40% of students at third level were operating at the highest level (Childs and Sheehan 2010). If these findings are generally true, it would have important educational implications, at second and third level.

The Irish second level educational system consists of a three-year junior cycle and a two-year senior cycle course. The senior cycle culminates with the Leaving Certificate (LC) examinations, which determine entry to third level education. The LC Chemistry course at is a two year course and is offered at Higher Level (HL) or at Ordinary Level (OL). The average age of the pupils beginning the Senior cycle is 16 and the recent work of Childs and Sheehan (2011) show that the percentage of Irish pupils operating at the formal operational level is actually lower than in the U.K. This means that most of these pupils start the LC Chemistry course without the ability to think in an abstract and conceptual manner. In teaching Chemistry, it is critical that educators are aware of the cognitive level and ability of their learners, who otherwise will become swamped by the multi-level cognitive demands of Chemistry (Johnstone 1991) as well as the other scientific and mathematical demands of the subject. Shayer and Adey (1981) devised a Curriculum Analysis Taxonomy (CAT) based on Piaget's work to classify curriculum objectives. This analysis found that pupils need to be at the formal stage of cognitive development in order to learn and understand core Organic Chemistry ideas. The same basic topics are common to all introductory Organic courses, including the LC Chemistry course. If the majority of second level pupils in Ireland have not yet reached the formal stage of cognitive development, it is not surprising that many topics are difficult for them, as was found by Childs and Sheehan (2009). When learners lack the cognitive ability necessary to learn and understand the topics encountered on their courses, alternative approaches may be adopted e.g. rote learning.

Organic Chemistry is a significant part of the Irish LC Chemistry syllabus (~ 20%) and the examination (~25%). The Chief Examiner's Reports (S.E.C. 2008) have recognised a tendency for Leaving Certificate candidates to avoid Organic Chemistry, even though this severely restricts their choice on the examination paper. This indicates a tendency by pupils or by their teachers to avoid a topic that they consider difficult.

The identification of Organic Chemistry as a problem area in Chemistry in Ireland and elsewhere provides the rationale for this work. The research questions aim to investigate more deeply what Irish second level pupils find difficult about Organic Chemistry and why.

- What specific areas of Organic Chemistry do Irish second level pupils find difficult?
- What specific areas of Organic Chemistry do second level teachers in Ireland find most difficult to teach?
- What are the causes for these areas of difficulty in Organic Chemistry?
- What teaching approaches contribute to the effective teaching and learning of Organic Chemistry?

METHODOLOGY

The Second Level Pupil Questionnaire (10 pages) took ~30 minutes to complete and contained two sections: Section A in the Second Level Pupil Questionnaire collected personal information from the participants and their previous Mathematics and Science experiences; Section B was a Diagnostic Test, with nine questions, each assessing a different Core Organic Chemistry topic from the LC Chemistry course. The test was designed to be answered after pupils had completed the Organic Chemistry section of the syllabus and assess the pupils' level of knowledge and understanding.. While some of the questions in the Diagnostic Test were designed by the author, some were also adapted from previous studies (Boa and Eames 2006, Brookes and Scott 1979, Reid 2003, Taagepera and Noori 2000).
The Chemistry Teacher Questionnaire was just two pages and took 10 minutes to complete; it had just one section and aimed to find out the teachers' perspective and approach to teaching Organic Chemistry, as well as their views of their pupils' perceptions.
Ethics approval was sought and granted from the University of Limerick Board of Ethics. Both questionnaires were piloted. A random sample of 100 schools was chosen for the study in April 2010, representative in school type and gender of the 546 schools teaching LC Chemistry in Ireland. In total 73 schools returned questionnaires: 35 (48%) of the schools had pupils and teachers who participated, while in the other 38 (52%) of the schools only the teachers participated. This resulted in a sample of 276 pupils and 79 teachers.
The questions and responses in each questionnaire (except for the free responses) were coded accordingly and inputted into SPSS Version 16.0. The data was first examined to view frequencies of responses; cross tabulations were then used to investigate what factors contributed to the participants' attitudes to and understanding of Organic Chemistry.

RESULTS

Second Level Pupil Questionnaire

258 (93.5%) of the pupils involved in this study were in sixth year and the remainder in fifth year Leaving Certificate Chemistry. 246 (89.1%) of the pupils were studying HL LC Chemistry. 165 (59.8%) found Organic Chemistry difficult. However, 158 (57.2%) enjoyed studying it and 124 (44.9%) agreed that it was interesting. 94 (34%) found it easy to learn: the main reason given by 41 (44%) of these pupils was that Organic Chemistry is logical and can be learned systematically. Many of these pupils also found the subject interesting and relevant to their own lives. In comparison, a greater number of pupils (165, 59.7%) found Organic

Chemistry difficult to learn. The most common reason for 52 (31.5%) for finding Organic Chemistry difficult to learn was the length and detail of the course.

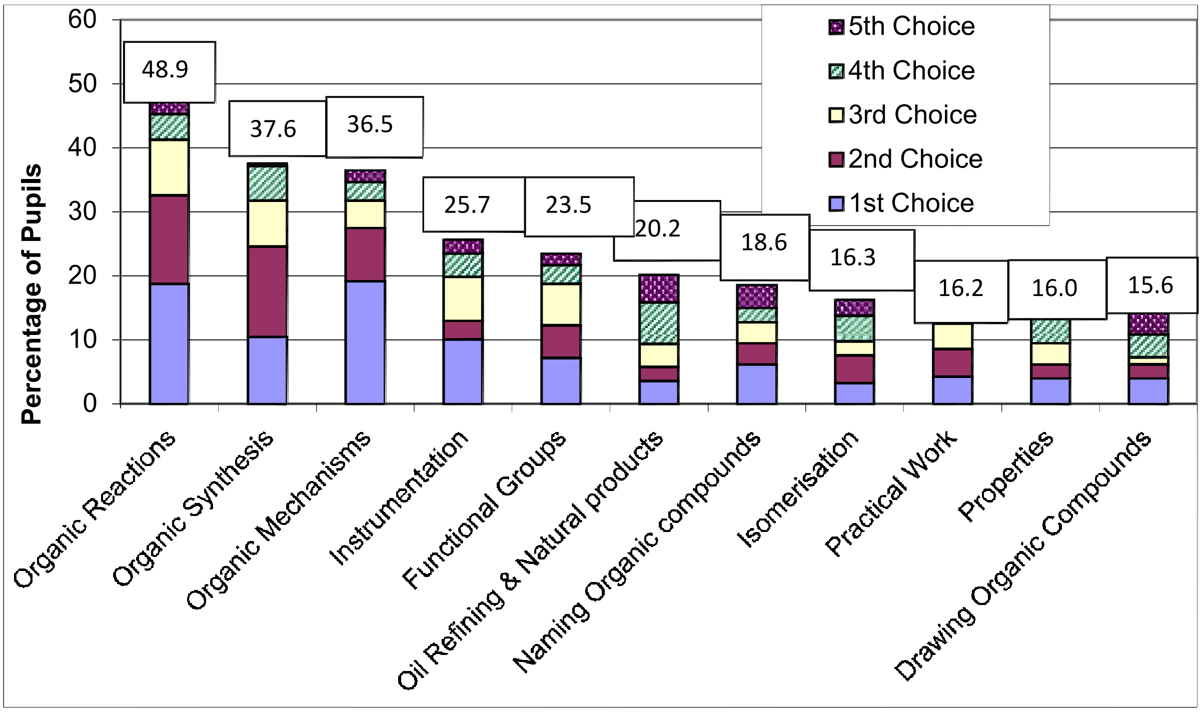

Figure 1. Top five most difficult Organic Chemistry topics as rated by second level pupils (n=276).

Difficult topics listed by pupils were: differentiating the functional groups, naming and drawing compounds; organic formulae; and reactions and mechanisms. It can be seen from Figure 1 that Organic Reactions, Synthesis, Mechanisms, Instrumentation and Functional groups were listed as the top five most difficult topics. Organic Mechanisms was listed as the number one most difficult topic by the highest number of pupils (53, 19.2%). However, Organic Reactions had the highest aggregate score as it was listed as difficult by 135 (48.9%) of the pupils.

The average number of questions attempted by each pupil was seven (out of nine). Taking the standard pass rate of 40%, 98 (35.5%) of the pupils failed the Diagnostic Test and 178 (64.5%) passed. The average score for the pupils involved in this study was 52.6%.
There was a difference of 5% between the male (49.4%) and female (54.3%) average scores, but this was not significant (p=0.161). Pupils studying Higher Level Chemistry scored an average of 36% more than those studying Ordinary Level. Also pupils who were studying HL Mathematics for their LC scored an average of 28% more than those studying OL. Pupils who had studied HL Junior Certificate Science scored an average of 36% more than those that studied OL. These differences were significant. Pupils who received higher grades in their HL Junior Certificate Science also attained higher scores in the Diagnostic Test.
Table 1 that follows shows a summary of the percentage of pupils who attempted each of the questions as well as the average score of each. Pupil perceptions of topics in Section A were consistent with their performance in the Diagnostic Test in Part B, with the exception of Naming Organic Compounds. This topic was poorly answered in the Diagnostic Tests despite being perceived as easy by pupils. Question 7 on Reaction Mechanisms was attempted by the least number of pupils and was the most poorly answered question in the test.

Question	Topic	Attempt (%)	No Attempt (%)	Average score (%)	Mark Order
1	**Drawing**	94.6	5.4	77	1
2	**Naming**	90.6	9.4	45	8
3	**Isomerisation**	84.1	15.9	66	2
4	**Electrophilic attack**	76.8	23.2	51	5
5	**Reaction Types**	81.2	18.8	46	7
6	**Reaction Synthesis**	66.3	33.7	47	6
7	**Reaction Mechanism**	51.1	48.9	29	9
8	**Classification**	77.2	22.8	56	3
9	**Properties**	72.8	27.2	55	4

Table 1. Summary of the pupils' performance in the individual questions. (n=276)

Chemistry Teacher Questionnaire

Most of the teachers agreed that Organic Chemistry is interesting and enjoyable to teach. Of the 67 teachers, 42 (63%) said it was easy to teach with 25 (38%) finding Organic Chemistry difficult to teach. The main reasons given by teachers who found Organic Chemistry easy to teach was that it is a logical topic (22, 54%) and also interesting and relevant to everyday life (16, 39%). The main reason given by the teachers who found it difficult to teach was the large amount of information to be taught in the syllabus (17, 68%). Even though the teachers felt that the pupils found Organic Chemistry interesting, they also acknowledged that the pupils don't find it easy to learn. 70 (87%) of the teachers answered the question about their pupils' perspective of learning Organic Chemistry: 53 (76%) of these teachers felt that their pupils find Organic Chemistry difficult to learn mainly due to the overload of information (27, 51%), and also the difficulty of distinguishing the functional groups (10, 19%). 16 (21%) of the teachers felt their pupils find Organic Chemistry easy to learn because of the logical nature of the organic families (12, 75%).
73 of the 79 teachers answered an open-ended question identifying the most difficult topics to teach. Instrumentation was listed as the most difficult topic to teach by 42 (58%) of the teachers. Reasons given by these teachers were the amount of information for the pupils to memorise, as well as difficulties in distinguishing between the principles and processes of the different techniques. 31 (74%) of these teachers associated the difficulty of teaching Instrumentation with the fact that many of them, as well as their pupils, had never used or even seen the instruments. The vague syllabus description of the topic also made Instrumentation difficult to teach. The second overall most difficult topic to teach was Organic Mechanisms (40, 55% of the teachers). The main reasons given by teachers for this were the difficulty of the concepts and the difficulty the pupils have in visualising the steps of the mechanisms. Mechanisms, Synthesis and Reactions are difficult to teach, as are Reaction Schemes, as they all rely on the pupils' understanding of functional groups and their characteristics. Many teachers have recognised the high cognitive demand of Organic Reactions, Mechanisms and Synthesis: these topics integrate all that the pupils have learned in Organic Chemistry. Many of the teachers recognised that their pupils' attempt to 'learn off' reactions and mechanisms because they have no understanding of the functional groups and transfer of electrons etc., and they cannot comprehend the abstract concept.

In the Second Level Pupil Questionnaire and Chemistry Teacher Questionnaire, common topics were identified as easy to teach and learn by pupils and teachers. While Classification and Isomerism were identified as 'easy to teach' by the teachers, they were not included as 'easy to learn' topics by the pupils. Isomerism and Classification were the second and third highest scoring questions in the Diagnostic Test, indicating the pupils' understood these topics even though they were not identified as 'easy to learn'.

Difficult topics	Chemistry Teachers' own Rating. (n=79)	Chemistry teachers' perspective of Pupils' Rating. (n=79)	Chemistry teachers' perspective of Pupils' Rating. (n=35)	Second Level Pupils' own Rating. (n=276)
Organic Mechanisms	2nd	1st	1st	3rd
Organic Reactions	3rd	4th	4th	1st
Organic Synthesis	4th	3rd	2nd	2nd
Instrumentation	1st	2nd	3rd	4th
Functional Groups	Not in top 5	Not in top 5	Not in top 5	5th
Isomerisation	Not in top 5	5th	5th	Not in top 5
Natural Products	5th	Not in top 5	Not in top 5	Not in top 5

Table 2. Top five most difficult topics as rated by Second Level Chemistry Teachers and pupils.

In Table 2, it can be seen that both teachers and pupils chose the same four out of their top five most difficult Organic topics, though not in the same order. The teachers' perspective are listed in two columns; one to represent all teachers involved in the study (n=79) and the other to represent the teachers teaching the 276 pupils involved in the study (n=35).

CONCLUSIONS

Johnstone (2000) recognised that what may be logical and simple to the Chemistry teacher, may not be so for the learner. To teach for understanding, teachers need to have an accurate awareness of their pupils' prior knowledge, misconceptions and level of cognitive development. If teachers have a better understanding of their pupils' opinions and attitudes, they may be better able to adapt their lessons to facilitate a deeper and more holistic understanding of the subject. The Chemistry teachers made a relatively accurate prediction of their pupils' attitudes towards Organic Chemistry in the Leaving Certificate. However, the teachers assumed their pupils held a more negative view of learning Organic Chemistry than they actually did. It is important for teachers to be familiar with their pupils' attitudes and approach to learning as well as their level of cognitive development and prior knowledge (Johnstone 2010). It is clear from this research that the topics listed in Table 3 are among the main topics that need addressing in designing new teaching materials. Other topics to be addressed include structural formulae, functional groups, characteristics of organic compounds and laboratory work.

The findings from this research have been used to design appropriate teaching materials to facilitate the teaching and learning of Leaving Certificate Organic Chemistry, in order to make it more interesting and accessible to pupils. Through trialling and evaluation of these materials (Sept-Dec 2011), this project will integrate the research and practice of Chemical Education and thus improve the teaching and learning of Organic Chemistry in Irish schools.

EXPERIMENTAL COMPETENCIES IN SCIENCE: A COMPARISON OF ASSESSMENT TOOLS

Nico Schreiber [1], Heike Theyßen [1], Horst Schecker [2]
[1] University of Duisburg-Essen, Germany
[2] University of Bremen, Germany

Abstract: Standards and models of science competencies refer to experimenting as an essential part of science education. Thus, valid assessment tools for experimental skills are necessary. Usually, written tests are used to measure these abilities. However, written tests exclude important process-aspects of experimenting (e.g. setting up the apparatus). The issue of validity arises. On the other hand, tasks with hands-on experiments are complex and resource-consuming. Assessment tools for measuring experimental skills in a process approach that are also applicable in large-scale assessments are desirable. The main goal of our project is to develop and to validate such tools. The development is based on a model of experimental competencies that focuses on process issues (e.g. assembling the experimental setup). Each student carries out one experimental task with a hands-on experiment and another task either with a computer-based simulation-workbench or with a computer-based written test. We regard tests with hands-on experiments as the benchmark for other forms of assessment. However, the other two methods are much easier to apply in large-scale assessments. We assume that for assessing experimental skills a simulation-workbench is closer to a hands-on experiment and thus more valid than a written test. To test this hypothesis, we examined correlations between students' scores in various subscales of experimenting gained by the three approaches.

Keywords: Experimental competency, assessment, hands-on experiment, computer simulation

FOCUS OF THE STUDY

Standards and models of science competencies refer to experimenting as an essential part of science education. Thus, valid assessment tools for experimental competencies are necessary. Usually, written tests are used to measure these abilities. Tasks with hands-on experiments are often avoided, because they are complex and resource-consuming. Written tests exclude important process-aspects of experimenting (e.g. setting up the apparatus). The issue of validity arises. Assessment tools for measuring experimental competencies in a process approach that are also applicable in large-scale assessments are desirable. The main goal of our project is to develop and to validate such tools. The development is based on a theoretical model of experimental competencies.

BACKGROUND AND FRAMEWORK

There are two established methods to assess experimental competencies: tests with hands-on experiments and written tests. Tests with hands-on experiments can be analysed with regard to the achieved experimental outcomes (Harmon et al., 1997; Adamia et al, 2008) or with regard to the process of experimenting (e.g. Neumann, 2004). Most large-scale assessments apply written tests, predominantly with multiple-choice-questions. Baxter and Shavelson (1994) examined the exchangeability of written tests and hands-on experiments. They additionally employed a computer simulation as a third test method. Shavelson et al. (1999) reanalysed the data of 1994. They compared three scores, which each test person achieved with (a) a computer simulation, (b) a written test and (c) a hands-on experiment. Only the results of the experiments were rated, not the experimental processes. The hands-on experiment was taken as the benchmark (direct observation and expert rating). The highest correlation existed between the benchmark and the analysis of the log sheets students produced during the hands-on experiment (r = 0.78). The least correlation was found between the benchmark and the written tests (r = 0.46). Shavelson et al. explain this low correlation with the missing direct feedback given by a written test. The correlation between the benchmark and the computer simulation was unexpectedly low, too (r = 0.50). Assessment is based on models of experimental competencies, e.g. by Klahr (2000), Hammann (2004) and Lunetta (2003). All these models describe three phases of experimenting: hypotheses, performance and analysis. Our model (Fig. 1) is based on these established models and focuses on the performance phase. The model does not imply a strict sequence of steps. The components can be passed in an iterative and not always complete sequence.

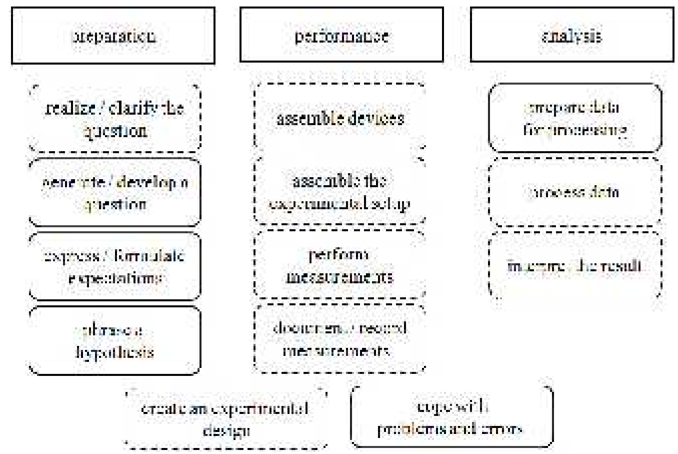

Fig. 1 model of experimental competence

RATIONALE AND METHODS OF THE STUDY

In this study we compare three different assessment tools for experimental competencies. They are based on hands-on experiments, written tests and computer-based simulation-workbenches. Each test person works in at least two different test environments. One of them is a hands-on experiment. Like Shavelson et al. (1999) we take the hands-on experiment as the benchmark for the comparison. In contrast to Shavelson et al. we analyse the students' *processes* of experimenting.

RESEARCH QUESTIONS AND HYPOTHESES

For each student we have at least two scores describing his or her experimental competencies on the basis of different assessment tools. Our main hypotheses refer to the correlations between these sets of scores:

H1: Written tests are insufficient predictors for hands-on tests ($r < 0.7$). This hypothesis directly follows from the results of Shavelson et al. (1999), who found a low correlation even though the authors only rated the experimental *outcomes*, without taking *processes* into account.

H2: Computer simulation workbenches are sufficient predictors for hands-on tests ($r > 0.7$). At first glance, the results of Shavelson et al. (1999) contradict this hypothesis. We expect a higher correlation, because we take into account the *processes* in both test formats and use technically more sophisticated simulations, which are very close to the actions in the hands-on experiments.

A further research question concerns the analysis of tests with the simulation-workbench:
Are ratings solely based on log-data that are generated by the simulation software as valid as ratings based on the video-analysis of screen recordings? A positive answer would facilitate large-scale assessments with this tool.

TASKS AND METHODS OF DATA COLLECTION

We developed three experimental tasks for the domain of electricity in secondary school curricula (e.g. to determine the voltage-current-characteristics of a bulb). In the hands-on experiments students have a set of scientific apparatus (more than the experiment affords) and a structured work sheet at their disposal. Students' actions are videotaped and the work sheets are collected. The simulation workbench imitates the hands-on experimental situation in a semi-realistic way. The work sheet is filled-in online. Data are collected by screen-recording and log-data recording (see research question). In the written version the test persons follow two fictitious students who work on an experiment. The test persons make decisions, what these students should do to solve the experimental task. The test contains multiple choice questions and open questions. It is presented online. In order to exclude consecutive faults, partial solutions are presented in the written test before a new sub-task is posed.

DESIGN OF THE MAIN STUDY

For the main study two tasks are implemented in the three assessment tools described above (hands-on experiment, written test, computer simulation). Figure 2 shows the design of the main study. In a pre-test, selected cognitive parameters were gained of 180 students (grades 10 to 12, upper secondary schools) by means of a questionnaire: content knowledge concerning electricity, general intelligence and spatial intelligence. Based on these data, four groups (matched samples) with about 35 students were put together. The students took part in a training-session, in which they were introduced to the apparatus of the tests, the handling of the simulation-workbench, and the handling of the written online-test. After the training-session they performed the actual tests as described in Figure 2. The design makes sure that each student performs one test with the hands-on experiment that we take as the benchmark for this study.

Classroom	Pre-test (selected cognitive parameters)

Fig. 2 design of the main study

DATA ANALYSIS

The methods for analysing students' performances were developed and validated in two comprehensive pilot studies with about 75 students. The piloting also tested the experimental tasks. First of all, a set of categories was developed with regard to the components of experimental competence (see Figure 1). The focus lay on students' actions while they carried out the hands-on-experiments or the experiments with the simulation-workbench. The category-based analysis showed that eight components of the theoretical model can be identified and separated in our test settings (see dashed boxes in Figure 1). Students' actions in these components can be encoded with a high inter-coder-reliability (Cohen's Kappa = 0.84).

The content validity of the category-based analysis was confirmed by interview studies. Eleven students carried out one of the tasks with a hands-on experiment or with the simulation-workbench. Stimulated recall interviews were conducted with the students directly after the tests. The qualities of students' actions were first coded by the category-based approach (data: videos or screen-recordings). During this first coding the rater did not yet know the interview data. Afterwards the same rater included the interview data for rating students' actions. The comparison of the two results shows a high content validity of the category-based-analysis.

The analysis of the *sequences* of actions gained from the hands-on and the multimedia settings yields that the sequences alone are not sufficient to rank students' experimental performance (e.g. for measurement). There are no simple surface action patterns indicating good or bad experimental performance. Hence, the *quality* of the actions has to be taken into account. The flow chart in Figure 3 exemplifies the coding scheme for the setup-phase. It illustrates how the coding decisions are made and how they lead to a quality index on an ordinal scale with five ranks. This *sequence analysis* leads to quality parameters for each student in each investigated model component and for each assessment tool. The reliability of this coding is high (e.g. Cohen's Kappa = 0.91 for the setup-phase). To validate this method, the assessments were compared with the results of a high inferent expert rating of the students' experimental competencies (Dickmann, 2011). The results show a high agreement (> 88%).

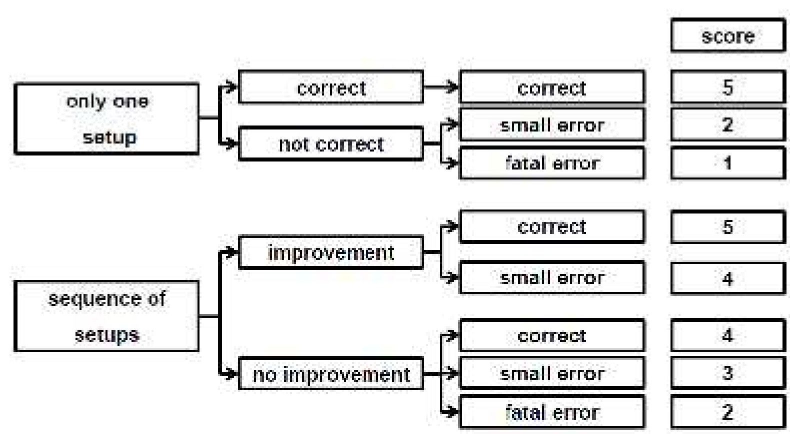

Fig. 3 flow chart for the assessment of students' achievements in the setup-phase

We also developed an algorithm that uses the log-data from the simulation workbench to encode the actions and sequences of actions automatically. Coding decisions according to Figure 3 (e.g. correct/not correct) still have to be made by human raters. But the semi-automatic analysis is less time-consuming and does not reduce the reliability of the final scores (Cohen's Kappa > 0.77).

RESULTS

To test hypothesis 1, correlations between students' achievements in the hands-on tests and in the written tests were calculated. There are significant correlations between the assessment from the written test and the assessment from the hands-on test, but they are very low (Kendall-Tau-b 0.35< 0.47) for all the model components.

To test hypothesis 2, correlations between students' achievements in the hands-on tests and in the tests with the simulation workbench were calculated. Again, all the significant correlations between the assessment from the hands-on test and the test with the simulation workbench are low (Kendall-Tau-b 0.28 < 0.55).

A qualitative analysis of the distributions of students' achievements shows a possible reason for the low correlations. The distributions show on the one hand a ground effect (too many students fail) and on the other hand dramatic changes in students' achievements from one task or assessment tool to the other. Figure 4 illustrates these findings for group 1 and the setup-phase.

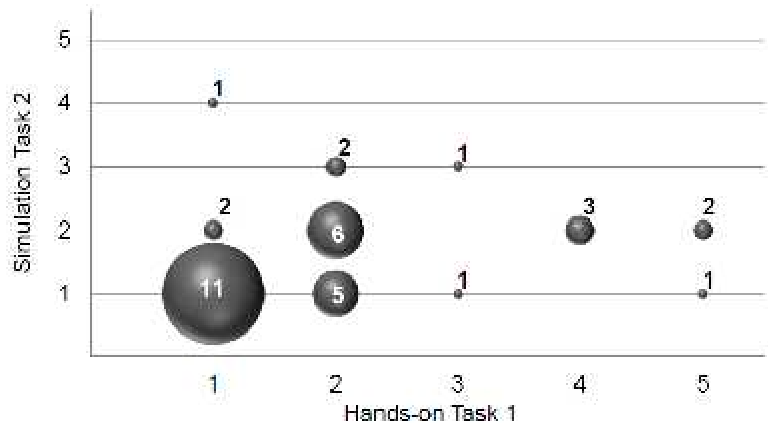

Fig. 4 bubble diagram of the scores for the setup phase for group 1 (Kendall-Tau-b: 0.337*)

DISCUSSION AND CONCLUSIONS

In this study applicable assessment tools for experimental competencies were developed as alternatives to hands-on testing. We also worked out reliable methods for a process oriented data analysis. For the simulation workbench test, an algorithm is available that automatically encodes the students' experimental actions with high reliability.

However, according to the present results, neither the written test nor the test with the simulation workbench is a valid substitute for the process-oriented diagnosis of experimental competencies in hands-on experiments. The observed ground effects in students' achievements show that the specific experimental tasks we used were too difficult for the majority of the students, although we had secured the curricular validity of the tasks and had had positive feedback from teachers, who expected their students to solve the tasks. The ground effects make the interpretation of correlations between the three test formats difficult.

On the other hand, the tests with the simulation workbench turned out to be practicable with regard to an implementation in large-scale assessments (together with the semi-automatic process oriented analysis). Compared to the hands-on tests, the qualitative analysis of students' actions shows very similar patterns of successful experimenting in students' actions and very similar mistakes. Obviously, the challenges and difficulties occurring during the experimental process are not caused by the assessment formats, but by the physics content. Further investigations with experimental tasks that produce a more balanced distribution of students' achievements are necessary to check our present findings. We keep the idea that simulation workbench tests are closer to hands-on tests than written tests.

Two questions arise from this study that have to be answered by further research:

Why are the correlations between students' achievements in the hands-on tests and the tests with computer simulations so much lower than expected?

Why do the students' achievements change dramatically from one task or assessment tool to the other?

One possible reason could be that the two experimental tasks – one posed in the hands-on setting and the other in the simulation environments – differ in their demands and difficulties. This assumption is not confirmed by our data. The distributions of students' achievements are similar when we look at group-accumulated data. The differences in achievements only occur when we compare achievements on the basis of the individual students.

Two possible reasons for our findings challenging the construct "experimental competence" are that (a) experimental competence is no coherent and stable trait behind students' performances or that (b) experimental competence is closely bound to the specific physics content of a task. Schecker (in press) argues in this direction. Whereas the first assumption puts the entire diagnostics of experimental competencies into question, the second assumption can be empirically investigated using a variety of experimental tasks from different content areas. Indeed, there are some investigations that support this idea of content dependency (e.g. Gott and Duggan, 2002). This leads to the question how many tasks from different content areas are necessary for a reliabel diagnostics of experimental competencies.

A LONGITUDINAL STUDY ON INTERESTS IN SCIENCE

Sabine Streller[1] *and Claus Bolte*[2]
[1]RWTH Aachen (Germany)
[2]Freie Universität Berlin (Germany)

Abstract: This article will introduce the concept and evaluation of an informal educational program aiming at arousing and furthering children's interests in science and improving their scientific competences regarding scientific literacy (Streller 2009).

The theoretical basis of our course design is the Educational-psychological Theory of Interest (Krapp 2002) and the Self-determination Theory of Motivation (Ryan, Deci 2000).
Since 2004, the learning opportunities have been offered to the children - independently from school and classes – in their free time on a weekly basis over a period of 2 years.
We have investigated the effect of the realization of this concept in longitudinal studies with control group design (N=382). In our investigation we used questionnaires - esp. the Motivational Learning Environment Questionnaire (Bolte 2006) - with several variables to get an insight into the development of interest and intrinsic motivation regarding science learning.
The findings show that the participation in these courses had a positive influence on the children´s interests in science and in learning science.
By evaluating our educational courses we are able now to provide recommendations for science education in primary schools. Furthermore, the findings show how evidence based links between science learning in school and in informal science learning settings can be created to foster the intrinsic motion of students to learn science and how to enhance students' sustainable interests in science.

Keywords: Motivation and Interest to learn science, informal science learning, longitudinal study, Science Learning Grade 4 to 6

INTRODUCTION

The importance of the natural sciences for general education is undisputed (OECD 1999). The German curricula for day nurseries and for science lessons in grades 5 and 6 both already include the foundations needed for later scientific education in view of scientific literacy. However, it seems that "basic scientific education in primary schools … is still difficult territory" (Marquardt-Mau, 2001, p. 85).

Hence we decided to develop an extracurricular educational program called "KieWi & Co.- Kinder entdecken Wissenschaft" (Children discover Science) with the aim of arousing and furthering children's interests in science and to improve their scientific competences. By developing, testing and evaluating our educational program, we try to provide suggestions and recommendations for science education in primary schools.

RATIONAL - THEORETICAL FRAMEWORK AND CURRENT RESEARCH

The theoretical basis of our course design is the Educational-psychological Theory of Interest (Krapp 2002) and the Self-determination Theory of Motivation (Ryan, Deci 2000). According to the interest theory, interest is conceptualized as a specific relationship between a person and a topic, an object, or an activity, which is characterized by positive emotional experiences and feelings of personal relevance. Interest-triggered actions are self-intentional actions, which can assume the form of short-term “interest” for a particular object (situational interest) or a long-term preoccupation with something (individual interest); leading to a relatively strong personality trait (Renninger 1998). Furthermore, because selecting areas of interest is a result of value judgments, the former become meaningful for the self-concept of a person (Hannover 1998).

The Self-determination Theory of Motivation is an approach to explain the support of interests (Ryan, Deci 2002). Self-determination is assumed to be experienced in environments that meet a person´s basic needs: the need for social relatedness, autonomy and competence.

To induce long-term interest-led actions of children, educational environments should be designed as follows: If it is possible to give the learner the opportunity to satisfy his or her inherent psychological needs for relatedness, autonomy and competence, interest-triggered actions will become more likely (Ryan, Deci 2000). Kunter et al. (2007) examined the effects of well-organized learning environments to support students´ interests in a subject and emphasize the crucial factor being how students experience their learning environment.

Following this theoretical framework, we come to three hypotheses:

Arousing interest in natural sciences can succeed,
- if the children´s suggestions and wishes are picked up in the development and realization of the courses,
- if it is possible to enable the children to have experiences of their own abilities and skills in the course of their dealing with natural sciences and
- if a learning climate is created where the children see themselves as socially integrated.

METHODS

Procedure of the intervention

As our intention is to increase children´s interests in science, one-day or other short term projects are impossible for our purpose because both the development of competencies and of areas of interest to form relatively stable personality traits requires active and repeated efforts on the part of the learner. In this way the 8 to 12 year-old participants take part in weekly courses that follow a systematic pattern and are designed for the long-term. In a period of up to two years they get to know scientific basics and ways of working by investigating age-appropriate problems in small groups. An example is shown in the following.

In the course unit “water”, the children are confronted with an everyday phenomenon (melting an ice cube in a glass of juice) and are asked to observe and describe exactly what they see. After watching the phenomenon the question arises what actually happens with the ice cube´s melt water. The children formulate three different assumptions: The melt water either sinks, collects at the surface, or mixes equally with the juice. Having formulated these ideas, the children independently start planning experiments to test their assumptions. Some children suggest using an ice cube of colored water to be able to follow the melting process in more detail. After carrying out their experiments, the children’s observations are collected and plausible explanations are discussed. At first it seems certain that the cold water sinks to the bottom of the glass; a result that is doubted by some children, however, since the cause for the melt water sinking to the bottom could be the higher density of the dye used. The children are now asked to plan and carry out another experiment to test this hypothesis. A deductive pattern of thought leads to the answer: warm colored water rises to the top in a beaker of cold water. If the dye was more dense than water, it would sink to the bottom of the glass.

This example shows how children can learn scientific ways of thinking on the basis of supposedly “unspectacular everyday phenomena”. The children can obtain a high degree of self-determination, autonomy and competence experience since they are able to follow and discuss their own ideas and do not receive prefabricated experimental procedures they simply have to follow step by step.

Procedure of the longitudinal study

Following the theoretical frame, a longitudinal study (including a control group) was the best way to find out how strong and lasting the resulting effects regarding the furthering of interests might be. We decided to use a questionnaire because of the following reasons:

First, to run a longitudinal study with more than 100 participants effectively, the use of a questionnaire is not as time consuming as interviews. A second advantage compared to interviews is the anonymity. In this way we hope to reduce answers regarding social desirability. To fill out a questionnaire and to agree or disagree to items is not simple for children but simpler than generating free answers (Rost 2004).

Therefore, we adapted a questionnaire and formulated the items in a children-appropriated language. Most of the items used are adopted from other studies (Table 1) and are well tested.

Variables relevant to the study in order of position in the questionnaire	Source of the items	Number of items
● **Socio-demographic data**		
● **Science-related activities during free time**	Hoffmann, Lehrke 1998 (supplemented)	7
● **Preferences concerning topic and**	modified after Bos u.a. 2005 (supplemented)	11
preferences concerning method		10
● **Motivational learning environment***	Bolte 2006	15
Satisfaction (emotional aspect)		
Willingness to participate (value commitment)		
subject relevance (object)		
Comprehensibility (competence)		
group cooperation (relatedness)		
opportunity to participate (autonomy)		
● **Self-concept regarding abilities**	Hoffmann, Bolte 2003	5
● **Attitudes towards natural sciences**	modified after Hoffmann, Bolte 2003	12

Table 1. Variables in the questionnaire; *six subscales, in brackets the relation with the pedagogical interest theory (Krapp 2002) and the self-determination theory (Ryan, Deci 2000)

There are two different versions of the Motivational Learning Environment (MoLE) questionnaire: The REAL version investigates the actual characteristics of the instruction in general and the IDEAL version investigates the desired characteristics (Bolte 2006).

Data sources

114 children in eight different KieWi groups (two groups of each round I-IV; Figure 1) filled out a questionnaire at the beginning of the KieWi course (t0), after each half a year of participating in the course (t1…t4) and half a year later (t5; follow up). 268 children from different schools (control group) were asked, too.

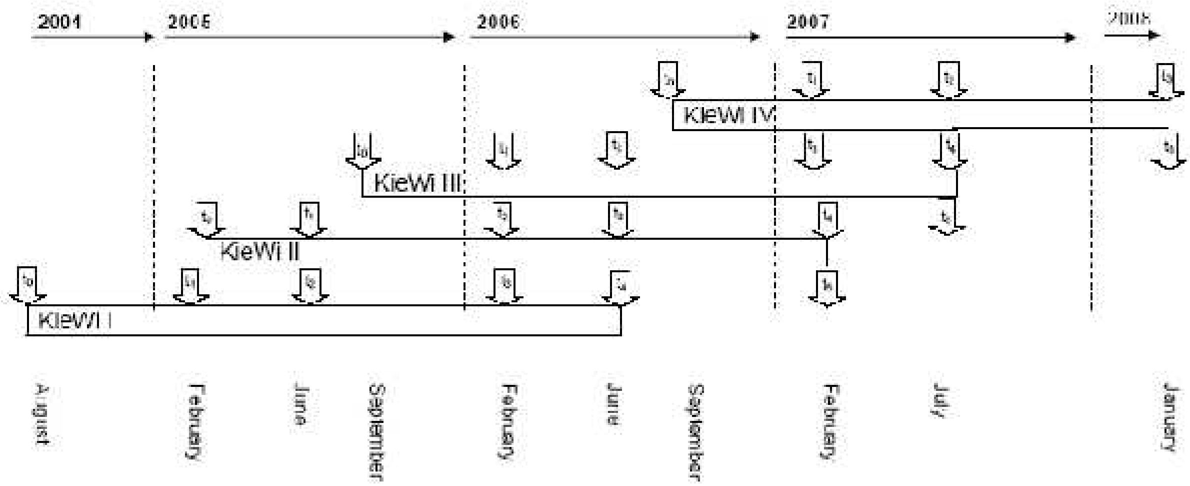

Figure 1. Schedule of the successive courses and times of data collection (arrows)

As may be expected of a longitudinal study, there are some missing data. If we take into our analyses and considerations only those students who took part in all of our data collections, we come to a sample as it is listed in Table 2.

Time of data collection	t_0	t_1	t_2	t_3	t^*_4	t^*_5	Control group
Number of children	114	95	75	64	46	33	268

Table 2. Sampling distribution, adjusted; *KieWi group IV missing cf. Fig. 1

Data analyses and homogeneity analyses

We used nonparametric tests for analyzing the data because of the ordinal measurement scale, the relative small sample and the not normally distributed data.

The sample of the KieWi children is a dependent sub sample, so we used the Wilcoxon test and the Friedman test for the analyses. But compared to the control group, the KieWi children (intervention group) and the control group are independent sub samples. Also independent from each other are the four KieWi groups I-IV. For analyzing these comparisons we used the Mann-Whitney U test and the Kruskal-Wallis test.

To summarize the data of the four different KieWi groups into one (to get a larger basis for the analyses), we calculated all possible pair comparisons to check the homogeneity of the different KieWi sub-groups. From all 351 comparisons we found only 14 significant differences. Because of this result the four KieWi groups are summarized into one for our further analyses.

RESULTS AND FINDINGS

During this study over nearly four years we collected a lot of data. Unfortunately it is not possible to show all of them, so we decided to give an insight into a selection of the findings.

Pupil's assessments of their self concept

The results of the scale self-concept with reference to natural sciences (α=.77) are shown in comparison to the children of the control group, differentiated according to grade (Table 3). In fact, the children who are going to take part in the KieWi course (t_0) and the children at the same age in the control group do not differ significantly in their estimation of their self-concepts of skills, but after one year this effect has increased (between t_1 ./. t_3 (Z = - 2,100 p <0.05) and between t_3 ./. t_5 (Z = - 2,019 p .043)). Regarding the KieWi children, a slight increase can be observed, whereas regarding the control group, a slight decrease can be observed. Furthermore, the variation of those estimations is becoming less for the KieWi children but larger for the control group children.

	self concept of abilities			
KieWi	**M**	**N**	**s**	**Md**
t_0	3.28	100	.483	3.4
t_1	3.24	73	.515	3.2
t_2	3.34	61	.482	3.4
t_3	3.34	61	.546	3.4
t_4	3.39	38	.367	3.4
t_5	3.45	32	.373	3.4
control group	**M**	**N**	**s**	**Md**
grade 3	3.18	22	.660	3.4
4	2.95	67	.630	3.0
5	3.08	42	.533	3.2
6	2.89	130	.651	3.0

Table 3. Changes of self concept from beginning (t0) to follow up (t5) of the KieWi children and the comparison of the KieWi results with the results of the control group (estimated and differentiated according to grade)

Item example: I often think I am not gifted enough.
strongly disagree (1) ...disagree (2) …agree (3) …strongly agree (4)

Pupil's assessments of their motivational learning environment

The scales satisfaction (IDEAL α=0.69; REAL α=0.81) as well as opportunities to participate (IDEAL α=0.72; REAL α=0.55) were ranked highest from KieWi children and control group children (Table 4).

	satisfaction			**opportunities to participate**		
	IDEAL	REAL	wish to reality difference	IDEAL	REAL	wish to reality difference**
KieWi	**M**	**M**	**ΔM**	**M**	**M**	**ΔM**
t_0	3.83			3.62		
t_1		3.69	.16		3.73	-0.08
t_2		3.61	.16		3.75	-0.17
t_3		3.68	.15		3.72	-0.19
t_4		3.74	.10		3.73	-0.24
t_5^*	3.68	3.34	.33	3.61	3.33	.26
control group	**M**	**M**	**ΔM**	**M**	**M**	**ΔM**
grade 3	3.58	3.65	-0.11	3.53	3.40	.03
4	3.73	3.53	.24	3.58	3.71	-0.18
5	3.62	3.26	.43	3.62	3.42	.22
6	3.57	3.20	.35	3.53	3.32	.18

Table 4. Changes of the assessments regarding two selected scales of the motivational learning environment from beginning (t0) to follow up (t5) differentiated by the intervention (KieWi) and the control group children *t5 applies to lessons in school

Item example REAL: *In the KieWi course, I feel…*
very comfortable ☐☐☐☐ *not comfortable at all*
Item example IDEAL: *To me, feeling comfortable in the KieWi course is...*
very important ☐☐☐☐ *not important at all*

The motivational learning environment in the KieWi course has been classified as positive in general. The KieWi children particularly appreciate their options to participate and pursue their own ideas. However, especially this point is missed in science education according to the KieWi children (t_5) who now assess their school science lessons, and according to the control group children.

Pupil's assessments of their methodical preferences

When asked for their methodical preferences in science education, distinct changes in the KieWi children's preferences could be observed (Figure 2).

Activities that allow for more self-determination (such as working in groups, experimenting independently) are more and more preferred. Activities such as watching the teacher doing an experiment or answering short questions of the teacher are more and more disliked.

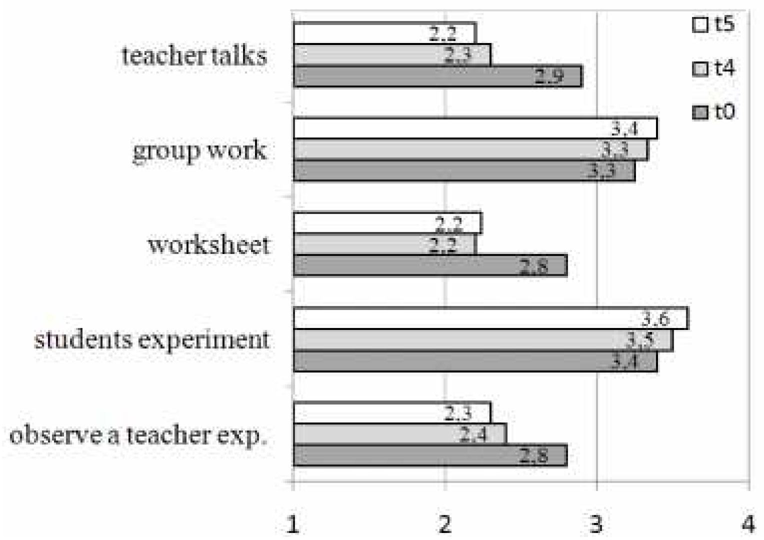

Figure 2. Changes of methodical preferences (a selection of 5 from 10 items is shown) from beginning (t0), after 2 years KieWi-course (t4) and follow up (t5)

Item example: *How do you like the following methods?*

very badly (1), badly (2), much (3), very much (4)

SCIENTIFIC AND SCHOLARLY SIGNIFICANCE OF THE STUDY

Our courses make it possible to positively influence the interests of the KieWi children to learn science. An increasing confidence in dealing with scientific data and tasks in specific ways is noticeable after a year of course participation. The children of the control group in primary school classes are also open-minded regarding the natural sciences and regarding science education and they, too, have confidence in their scientific capabilities particular in early grades. But comparing the results of the grade 5 control group with those of grade 6 it becomes obvious that this confidence decrease from grade 5 to grade 6.

On the basis of the positive findings in the survey of the KieWi children, we want to test now course sequences of the KieWi courses in regular school science lessons. Consequently, the question arose in what way the concept of the KieWi & Co. courses can actually be transferred to primary school. To find an answer to this question we have already started cooperations with primary schools and primary school teachers and established a long term teacher training with monthly workshops (Streller, Erb, Bolte, in press).

CHEMISTRY-SPECIFIC LANGUAGE AND HOW IT INFLUENCES UNDERSTANDING OF CHEMISTRY CONTENT

Nermin Tunali and Elke Sumfleth

Abstract: The purpose of this study is to investigate if competence in chemistry-specific language is a pre-requisite for achievement in chemistry and if advancement in chemistry-specific language facilitates content learning. Therefore, data will be collected with a pre-post by control group design from a thousand grade 7 students at upper secondary schools and comprehensive schools in North Rhine-Westphalia. In the pre and post test students' language skills in the school language (L_S) and in the chemistry-specific language (L_C) will be measured and an achievement test will be administered. In addition, in the pre test data on cognitive abilities, interest and social background will be surveyed to serve as control variables. To measure the level of chemistry-specific language a C-Test was developed and will be used. In the training study one group will be trained emphasizing the acquisition of chemistry-specific language and the other one will be trained with a more traditional emphasis on chemistry content. Finally, the results of this study will give hints how to construct subject-specific language- sensitive assignments and how to support students' subject-specific language skills.

Keywords: school language, chemistry-specific language, chemistry achievement

1. INTRODUCTION

The results of international large scale assessment studies such as TIMSS and PISA confirm the importance of language skills, in this case of German as the language spoken at school, to follow the lessons at German schools, to learn contents and at the same time to be able to acquire key competencies (Hopf, 2005; Prenzel et al., 2005; Ramm et al., 2004). These studies show that students in Germany, regardless of a migration background, have difficulties in subject-specific text comprehension. Although the results concerning reading skills of students with migration background have improved significantly from PISA 2000 to PISA 2009, the difference between students with and without migration background remains big. Another important result of PISA 2009 is that the influence of the language spoken at home on reading skills has decreased. In PISA 2000 students who spoke a language other than German at home earned 60 points less in reading skills compared to native German students, while the difference in PISA 2009 has decreased to 24 points. This improvement can be explained by an increased focus on support of language skills since the publication of PISA 2000 (Stanat et al., 2010).

Everyday language is different from subject-specific language (Spanhel, 1980; Priesemann, 1971) or the language which is used in textbooks, which predominantly equals subject-specific language. Therefore, understanding the key concepts of the subject is not only difficult for students with migration background (Deppner, 1989) but also for German students. So, they should be supported in their language skills, too (Baur & Spettmann, 2007). In addition, in a comparison of students with Turkish migration to students with different migration backgrounds, Turkish-stemming students were outperformed with regard to their basic language skills in German (listening, speaking, reading and writing) (Köller, Knigge & Tesch, 2010). Accordingly, students with and without migration background should be empowered to use everyday language competently as well as they need to learn the subject-specific language to learn content knowledge. Subject-specific language is not a part of everyday language. Therefore the students should be trained explicitly how to use subject-specific language (Lemke, 1993).

Above all, the project's focus is on linguistic aspects of science education. Merzyn (1998) points out that learning is depending to a high degree on linguistic performance. Likewise, Yore and Treagust (2006) emphasize that students have to be able to use basic language skills to be able to learn the subject content. This problematic interference of language worsens even as students have to learn an additional subject-specific language in chemistry classes. Learning a subject is always inextricably linked with learning its language. Classes can address these issues on two different levels, the level of spoken language and the level of written language (Merzyn, 1998).

2. METHODS

2.1. Hypotheses

The purpose of the study is to investigate the effects of a competent use of subject-specific language on learning chemistry content and the differences caused by language skills between students with and without migration background. Thus, the following hypotheses will be tested:
H1. Students who use chemistry-specific language (L_C) more competently perform better in chemistry.
H2. Students who are trained specifically in chemistry-specific language are better in chemistry than students who have worked only on the chemical content.
H3. Students who are trained specifically in chemistry-specific language are better in chemistry-specific language than students who have worked only on the chemical content.
H4. Students who are trained to use subject-specific language will improve their use of school language (L_S).

2.2. Design

The presented study consists of two parts and is conducted with a pre-post design.

Part A: Selection of students for the training study

The total sample consists of 1000 grade-7-students from upper secondary schools (German *Gymnasium*) and comprehensive schools (German *Gesamtschule*). In order to measure the language skills in the school language (L_S) and in chemistry-specific language (L_C) C-Tests (see Chapter 2.3.) are administered. Moreover, chemistry achievement data are collected. In addition, in the pre-test data are collected with regard to the following control variables: cognitive abilities, interest and a questionnaire on socio-economic background. Students who will be supported in their chemistry-specific language acquisition will be divided in groups on the basis of the results of a chemistry-specific language test (C-Test L_C) and a school language test (C-Test L_S) (see Figure 1).

Pre-Test C-Test L_S, L_C , achievement test, cognitive abilities test, interest, socio-economic background questionnaire		
Level of language	**Training**	
	Training focusing on content knowledge in chemistry	Training focusing on chemistry-specific language
L_s (+) & L_c (-)	**A**	**B**
L_s (-) & L_c (-)	**C**	**D**
L_s (+) & L_c (+)	**E**	**F**
Post-Test C-Test L_S, L_C, achievement test		

Figure 1: An overview of design and instruments

Part B: Training study

Based on these data, six groups (A, B, C, D, E, F) of 100 students are formed. Each group ideally is composed of 50% German-speaking students and 50% Turkish-speaking students (see Figure 1). Subsequent to the intervention, students who have been specially supported in learning the subject-specific language in chemistry will be compared in their learning achievement with students who have worked with a more pointed emphasis on the chemistry content.

2.3. Instruments and teaching materials

C-Test:

C-Test (Cloze-Test) is based on the principle of *reduced redundancy* (Klein-Braley, 1997). To date, various types of C-Tests which are based on this principle have been developed and used (Baur & Spettmann, 2007; Grotjahn, 2006; Coleman, Grotjahn & Raatz, 2002). In this study, a C-Test for grade 7 (Baur & Spettman, not published) will be used to measure language level in the school language (i.e. German).

The C-Test typically consists of a collection of four texts, each of which embraces twenty to twenty five gaps (80-100 gaps in total) that need to be completed by the students. In each of the texts, every sentence but the first and last sentences are affected by gaps. These gaps are formed by deleting the posterior half of every third word in the sentences (cf. Baur & Spettmann, 2007).

In order to measure the language level in chemistry-specific language an analogous C-Test L_c has been developed. In this C-Test L_c, only chemistry terms will be transformed into gaps. For this purpose, chemistry textbooks which are used at upper secondary schools and comprehensive schools have been analyzed concerning the chemistry terms used in them. The results of this expert rating distinguish chemistry specific-terms satisfactorily from non-specific terminology ($\kappa = .76$; Wirtz & Caspar, 2002).

Teaching materials for the training:

Worksheets for both training groups have been developed. The same content is taught in both groups including these topics:

- Material and their properties
- Physical states of matter

- Mixtures and solutions
- Separation processes

The worksheets that will be used to support the chemistry-specific language were developed according to Leisen (2010).

3. PRELIMINARY RESULTS OF THE PILOT STUDY

The total sample of the pilot study consists of 95 grade-8-students from comprehensive schools. They have learned with the worksheets for ten weeks. After the training a positive correlation between the chemistry achievement and the performance of chemistry-specific language was found. In addition, there is a correlation between school language and chemistry-specific language, but just for the topics "Materials and their properties" and "Physical states of matter" (see Figure 2). This relationship can be explained by the similarity of terms with the everyday language. For example, the term "color" features in the subject area "Material and their properties" as a chemical term but students use the same word also in their everyday language. Likewise, the low learning growth in the subject areas "Material and their properties" ($t(42) = .211$, $p = .834$) and "Physical states of matter" ($t(39) = -.831$, $p = .411$) could be explained with these overlaps of everyday language and chemistry-specific language.

Post-Test	
Chemistry achievement – Chemistry-specific language	**Correlations**
Materials and their properties & Physical states of matter	$r_S = .399^*$, $p < .05$
Mixtures and solutions & Separation processes	$r_S = .334^*$, $p < .05$
School language – Chemistry-specific language	
Materials and their properties & Physical states of matter	$r_S = .424^{**}$, $p < .01$
Mixtures and solutions & Separation processes	n.s.

Figure 2: Spearman's correlations

Furthermore, comparisons of means indicate a significantly higher learning growth for the group trained in chemistry-specific language. Yet, this finding is restricted to the topics "Mixtures and solutions" ($t(25) = 3.181$, $p < .01$) and "Separation processes" ($t(14) = 2.301$, $p < .05$).

4. DISCUSSION AND CONCLUSIONS

The preliminary results of the pilot study show that the chemistry-specific language has an influence on the chemistry achievement. In addition, the results provide evidence that there are differences and overlaps between school language and chemistry-specific language. Moreover, the results show that the training on chemistry-specific language produces positive effects in the subject areas "Mixtures and solution" and "Separation process" concerning the competent use of chemistry-specific language. Based on results of the pilot study the worksheets for the subject areas "Mixtures and solutions" and "Separation process" will be used in the main study to examine the effects of the training on chemistry performance, school language and chemistry-specific language.

PLAY WITH SCIENCE IN INQUIRY BASED SCIENCE EDUCATION

Maria Andrèe[1], *Lotta Lager-Nyqvist*[1] *and Per-Olof Wickman*[1]
[1] Department of Mathematics and Science Education, Stockholm University, Sweden

Abstract: In science education students sometimes engage in imaginary science-oriented play where ideas about science and scientists are put to use. Through play, children interpret their experiences, dramatize, give life to and transform what they know into a lived narrative. In this paper we build on the work of Vygotsky on imagination and creativity. Previous research on play in primary and secondary school has focused on play as a method for formal instruction rather than students' spontaneous informal play. Our aim is to explore students' informal play as part of activity in lower secondary school science. The empirical study was conducted as part of a larger study on learning, narrative knowing and remembering in inquiry based science education in two Swedish compulsory schools. Data were collected during 10 weeks using video- and audiotape recordings. Our analyses of play show that the students step in and out of play when engaging in task completion. Play offers opportunities for sense-making, opposition and exploration of ways of enacting science identities. Implications for teaching science are that teachers, in order to promote students' learning about science as a cultural endeavor and students' learning about themselves in relation to science and scientist communities, may encourage students' informal play.

Keywords: informal play, science learning, inquiry, lower secondary school

BACKGROUND AND FRAMEWORK

Lisa:	Now I'll do.
Gustav:	Here doctor, thirty seconds.

The above excerpt is an example of sixth grade students engaging in play activity along with their completion of a laboratory task of testing for glucose in different nutrients in 6th grade science class in a Swedish compulsory school. Gustav and Lisa engage in role-play of a doctor and an assistant. Lisa puts the testing stick in the investigated food and Gustav counts to thirty. This play involves making use of what they know about testing, possible social roles and science culture. Through play, children interpret their experiences, dramatize, give life to and transform what they know into a lived narrative. Children's play is not just simple remembering but a creative transformation of the experienced – creating a world that meets the needs and interests of children (Vygotsky 1930/2004). In science education students sometimes create and engage in imaginary science-oriented play where ideas about science and scientists are put to use. Students create imaginary situations by combining experiences available to them; be it personal experiences or someone else's historical or social experiences made available through narratives, literature, media etc (Vygotsky 1930/2004). These play activities open opportunities for students to explore ways of positioning themselves in relation to science. A scrutiny of informal play activities is therefore also a scrutiny of science classrooms as places where identities are developed through students' engagement in activity (cf. Kelly & Sezen 2010; Wenger 1998).

Here, we investigate students' self-initiated spontaneous play as part of everyday culture in science education, how it emerges and in what ways it opens up for students to explore ways of positioning themselves in relation to science and science education. Our aim is to explore students' spontaneous informal play as part of activity in lower secondary school science in order to contribute to our understanding of processes of learning science in school science practices.

Previous research on play and science learning

There is an extensive literature on play in general in particular related to pre-school (e.g. Lindqvist, 1996; Moyles 2005; Singer, Hirsch-Pasek & Golinkoff 2006). In relation to science education, however, research is rather scattered. In our review of previous research we discern different approaches to the analyses of play and science learning which may, at least partially, be understood in relation to the researchers being engaged in studying different parts of the educational system.

In relation to compulsory school science education there has been an interest in play as part of instruction in terms of role-play and computer-games. McSherry & Jones (2000) argue that role-play in science lessons is underrated and underused and attempt to provide a theoretical basis for the use of role-play as part of developing the experiential side of teaching science. Simulation-role-play is held by Aubusson, Fogwill, Barr and Perkovic (1997) to allow students to demonstrate their understanding, explore their views and develop deeper understanding of phenomena although they raise concerns about students' capacity to distinguish role play from the subject matter being studied. Burton (1997) provides detailed steps to guide teachers through the process of role-play in order to enhance learning in science. With the growth of educational computer games and programs emphasis has been placed on play with computer programs (as game-play) as instructional method (Roussou 2004; Steinkuehler & Chmiel 2006; Barab, Sadler, Heiselt, Hickey & Zuiker 2007).

In pre-school, play – in particular 'free play' – has been recognized as an important part of learning in general ever since Friedrich Fröbel's work in the early 1800's (Lindqvist 1996). The role of the pre-school teacher is described as a facilitator of children's play (op cit). In relation to science learning there are few studies of play. Henniger (1987) analyzes learning opportunities in science and mathematics available through children's play. In particular he studies what attitudes to learning science are developed through play. However, Goldhaber (1994) reports on pre-school teachers expressing insecurity in relation to whether children may be allowed to play if the activity is to be called science.

In relation to learning science at university, Hasse (2002) has shown that play as science preparation is very much part of learning physics. She showed that games, like creating new experiments rather than adhering to given tasks, prepare students, boys in particular, for lives as scientists, and allow students to play out their imagination.

The research initiatives on play and science education differ in relation to different forms of education. Hasse's (2002) study on play in university physics focus on informal play as an integral part of learning science whereas studies of school science focus on formal instruction. Research on play in pre-school science take a semi-formal approach recognizing informal play as mediating formal learning. However, there is little reason to expect that informal play would be of less importance as an integral part of learning science in school as compared to learning science at university. Even though there may be important differences relating to the goals and motives of educational activity in different forms of schooling.

Play in a Vygostkian perspective

Here, we use Vygotsky's notion of play as imagination in action to develop a framework for discerning and theorizing moments of play in the science classroom. Vygotsky elaborated the theory of play in his essay "Play and its role in Mental Development of the Child" (1933/2002) and in his book "Imagination and Creativity in Childhood" (1930/2004). Vygotsky characterizes play in terms of involving 1) an imaginary situation and 2) rules implicit in the imaginary situation. Through play imagination is enacted socially and collectively. The imaginary situation created in play is free of constraints of the real situation and allows the child to meet its desires (Vygotsky, 2002).

Vygotsky (2004) argues that it is not possible to draw a strict line between imagination and reality. Everything created by imagination is based on elements in reality, from a person's previous experiences or experiences shared by other people (op cit). However, children's play is not a simple reproduction of prior experiences but a creative reworking of experiences which is combined to construct a new situation that conforms to the child's own needs and desires (op cit). Thus, imagination becomes a means to broaden a person's experience because he can imagine what he has not seen and may conceptualize something from another person's narration and description of what he himself has never directly experienced (cf. Ferholt, 2007).

RESEARCH QUESTIONS

This paper reports from a larger study on learning, narrative knowing and remembering in inquiry based science education (IBSE). Hence, we focus specifically on play in IBSE. The main research questions addressed are: How and when is play initiated by students in lower secondary IBSE? In what ways is play used by students to overcome situational constraints? What affordances do students' engagement in play open up for?

METHODOLOGY

The study was conducted in two Swedish compulsory schools (school A and B). School A is situated in a relatively prosperous residential community and school B in a less advantaged suburban community. In each school we followed one teacher and their 6th grade class working with the unit 'Chemistry of food' in the curriculum material *Naturvetenskap och teknik för alla*, NTA (in English *Science and Teachnology for all*). The unit covered a period of about 10 weeks. Data were collected throughout the 10-week-period using video- and audiotape recordings of classroom work (in all app. 55 h). The audiotape recordings were transcribed verbatim with the video recordings used as support.

Vygotsky's (2002; 2004) theory of play has provided the beginning point for examining play and/or invitations to play in the studied classrooms. We have operationalized play in our analyses of data as situations where at least one of the following criteria is met:

- a student tries to act as someone i.e. positions him- or herself *as* someone,
- a student positions a co-student *as* someone,
- an object becomes pivot i.e. separated from its original meaning and ascribed new meaning in an imaginary situation and
- a student enact rules/norms of action that transcend the given tasks.

When analyzing play we have been looking for play and invitations to play. Important to note is that invitations to play sometimes fail.

RESULTS

Play with science and tasks of the science classroom appear to be an integral aspect of the everyday culture of the school science classroom. In data of students working with investigating *the Chemistry of food* we found several examples of play or invitations to play even though it is evident that play is not a leading activity. Out of the 26 analyzed group discussions there is play or invitations to play in 10 groups. Our analyses of play show that the students step in and out of play when engaging in task completion. Albeit transcending some situational constraints the students enact play within boundaries of given school tasks. Students engaging in play are simultaneously well attuned to constraints of task completion. Play offers opportunities to explore e.g. different ways of positioning as a researcher, a doctor, an assistant.

In the following we will exemplify our analyses by means of the introductory transcript of doctor-assistant play. In this example play emerges as a subtle process where Lisa and Gustav initiate play by use of a slightly different tone of voice or gesture. Lisa and Gustav begin initiating a doctor-assistant play in setting up a division of labor; in the way they deal with the measuring stick and the food to be investigated. They start taking turns measuring with the measuring stick and pouring the food in a cup: "I'm supposed to pour out and you take the stick". Some minutes later they switch.

Gustav then makes the play situation explicit in a comment on a negative test result saying: "None of these substances here have glucose. Is this normal? No, I'm kidding". When saying "is this normal" with a lower more formal tone of voice he steps into the doctor position of the play. By the following comment that he is kidding, Gustav marks his previous utterance as play and again steps out of the play situation.

The play situation is brought to the fore again ten minutes later when Lisa takes over the responsibility for measuring:

Lisa:	Now I'll do.
Gustav:	Here doctor (hands the measuring stick to Lisa) thirty seconds.

The studied IBSE practices offer students a relatively rich variety of resources combined with a lesser degree of discursive control as compared to whole-class teaching. These conditions open up possibilities for students to engage in self-initiated play. Resources that become pivot are both measurement instruments (e.g. the stick for measuring glucose) and objects of students' investigations (e.g. wheat flour in a case where a girl invites her group mates to play that they are preparing a dough to bake buns).

We find that the students in our studied classrooms step in and out of play when engaging in task completion. E.g. a group of boys create an imaginary situation when they measure fat in water. These boys play with the idea of actually discovering fat in water and the possibility of receiving the Nobel Prize. They explicitly negotiate the play situation and explicitly step in and out of the play situation.

CONCLUSIONS AND IMPLICATIONS

In conclusion, imagination and play are important dimensions of classroom life. Our findings contribute to the understanding of how learning in the school science classroom is embedded in social and cultural-historical practice, and how individual students' engagement in play contribute to transforming and transcending classroom practice. Play offers students opportunities for creating situations in the school science classroom that meets the needs and interests of the students. Play offers opportunities for sense-making, opposition and exploration of ways of enacting science identities.

When students engage in play they transform the given tasks in relation to needs and motives that are personally meaningful to them. Hasse (2002) showed that play activity is part of university physics students' preparation for a scientific career and that play enable students to learn hidden rules of science. Our examples of play in the lower secondary IBSE classroom are not only examples of ways of making meaning in relation to becoming a scientist but also examples of students distancing themselves in relation to the science content as in game-play. A teacher may promote students learning about science as a cultural endeavor by facilitating and encouraging students' exploration of different ways of positioning themselves in relation to science and a community of scientists in spontaneous play.

This study opens up for further studies on play as an aspect of everyday school culture. When we have analyzed our data a feel emerged that students who do engage in play have more fun in the science classroom. Investigating students' trajectories of play in relation to participation and motive development is one question for further research that may advance educational researchers' understanding of education.
